50729. RE: [TS-520_820_530_830] Re: TS-530SP RF Gain

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-01-01 05:37:26 UTC
From: Thomas Gugler
Topic: 50591 Message: 50729

Terry,

Final update on this thread, (I hope). I threw in a 3SK35 MOSFET into the Q4 slot since I have a number of them from working on TS-520's, just as a proof of concept.

Radio came alive – S Meter seems to function normally, RF Gain control acts as it is supposed to, and AGC slow / fast action is okay as well.

Rig actually sounds quite good – had a number of QSO's on 75M with it tonight.

I did order a NOS Toshiba 3SK73 – it should arrive in a week or so and will swap out my temp fix.

I want to thank you very much for your time, patience, and insight in helping me troubleshoot the radio.

This is a great group and wonderful resource for the old KW Hybrids.

Also, want to wish you and everyone in the group and happy and prosperous New Year.

Regards

Tom

W7OA

Subject: RE: [TS-520_820_530_830] Re: TS-530SP RF Gain

Yes certainly should not have standing 500 ohms on the AGC bus.

Very unusual for one of the IF amp dual gate mosfets to go bad.

Besides the meter FET and the gain controlled devices you also have the AGC amp transistor Q6 hanging off the bus at all times. I am inclined to believe it is the culprit and not one of the AGC timing caps. Either it is bad or is biased on all the time. Take a look at Q6. Also make sure you have good -6vdc to it and not just at the Molex Conn 12.

Terry K9TW

50730. RE: [TS-520_820_530_830] Re: TS-530SP RF Gain

Tom:

Glad you found it. Most common fault is the meter FET pulling AGC bus down.

I can tell you that it is very rare for one or more of the dual gate Mosfet IF amps to be bad. Only exception is the one in the RF amp position as it is subject to nearby lightning and inadvertent transmit RF. I dont think I have ever replaced a bad IF amp mosfet.

Q2 sees double duty serving as an IF amp and the TIF amp. In that service it sees both the AGC bus and the ALC bus voltages. I am wondering if you had an event that saw high voltage on the ALC bus line? It is pretty rare but 6146 arc over to the control grid results in transient down the FG line back to ALC amp and the ALC bus. In rare event that this happens Q2 is taken out and usually Q31 on audio board. KW was concerned about it so they installed a transient suppressor on the FG lead at the audio board.

If your ALC is working in TX mode then not likely the cause of Q2 failure and no relationship to Q4 failing. Probably will never know the root cause. Possible they just got tired, but I have never seen it.

Enjoy your 530SP. I have two here now on the bench (pegged ALC and no RF output) and just bought one that I will probably keep as a reference rig.

Well this just happened (great way to start off the new year)
I was tx on 15 meters when I heard a POP, then all output power was lost...I'm not good at all with tracking down problems, but I have the case off and looking for anything that might have popped I'm seeing nothing.
The radio WILL NOT tune up an any band (no output power)....
Thanks for any help that I get
Dave KG6SVF

Dave,

Place the meter switch to IP, Mode to USB or LSB, MIC Gain fully CCW, then press the microphone's PTT button and at the same time, look at the TS-530's meter. If the meter pointer rests at zero then most likely the four 20 ohm 1/2 watt final amplifier cathode resistors have failed, burnt open.

You will have to remove the top and bottom covers, place the TS-530 upside down with the front panel facing your right. This will put the final amplifier on your left. Look for burnt/open cathode resistors, there are 4 of them.

You can find replacement resistors at various electronic parts outlet such as Mouser, Digikey, Ebay, and also at Ken, K4EAA, website

Dave,
I agree with Mike, with but one exception:
  The resistors in question are not visible from the bottom of the rig, unless you flip the final amplifier board over. They are on the top side of the final amplifier board and not visible from the bottom

Turn OFF and UNPLUG rig..let sit of a bit. Remove top and bottom covers. Remove the screws that hold the final amplifier cage cover in place. Test for high voltage from the top of the plate choke (the tall white ceramic thing wrapped with copper wire) to ground. There needs to be NO VOLTAGE present. Remove the plate caps on both final amp tubes, remove tubes, and with a bright light look down into the top of the board...you should be able to see if any of the resistors in question are popped open. You should also be able to check them by using any multi-meter set to OHMS X1 and test from pin 1 of the front tube to ground. You should read about 5 ohms or so. Any reading significantly higher...say 6+ohms, will indicate that one or more resistors have failed.

Good Morning and Happy New Year,
I have a 520S I had used for 160 M receiver that I no longer need. I have disconnected the HV from the PA tank and all tubes are removed but it is 90% complete. It would not take much to get back on air or would be a good rig for parts. I have no desire to repair it or use it any longer. If anyone is interested in it, shoot an Email my way off reflector. Otherwise it goes to the storage shed.

Okay Dave,

Here's what the Final Unit PC board looks like after you remove the
mounting screws and turn the board over to see the resistors:

Simply remove the mounting screws holding the final amplifier PC board
to the chassis and gently turn the board over and you will see the four
20 ohm cathode resistors.

Note the picture showing the four 20 ohm cathode resistors. The color
bands will be RED/BLACK/BLACK (20 ohms). Each resistor is 1/2 watt. If
the resistors have burnt open then you probably won't be able to see the
color bands.

Please note that you will have to unwrap the blue wire from the "DRV" post on the final amplifier board to be able to turn over the board. You can usually use some needle-nosed pliers to partly unwrap the wire and carefully pull up. Just don't forget to reconnect it when done!!

Dave,

Pay close attention to what Joe and Mike are telling you about draining high voltage in and around the cage.

I'll weigh in on this as it sounds like you are in about the same situation as I was, skill-wise, with maybe the exact same problem. I have an 830S which lost power suddenly. i didn't get a pop, just high IP current to get decent output.

I was very timid about doing the repair myself. I had been in touch with Dick Housden W0NTA who repaired the wafers on my RF board. He told me where to measure resistance. I measured 9.4 ohms so we knew one or more the 4 cathode resistors went south. Correct reading is 5 ohms. I had the parts on hand from Ken K4EAA.

To fix it, mark and remove the tubes (front and back - didn't want to take any chances...). Remove the board screws and carefully route the wires so that you can turn the board about 45 degrees. That gave me enough room to remove the 4 resistors and install the new ones from the top using tweezers. This way you won't disturb any factory wiring. It was a daunting task to think about but the actual operation went smoothly. If you don't have a desoldering tool like a Hakko or Aoyue, borrow one. It is VERY easy to lift a pad off of these boards with a solder sucker. I know, I did it on my SM-220. That's when I bought a Hakko FR300. Pricey but cheaper than sending the rig off for repairs.

Reassembled, tested resistance at 5 ohms, fired up the rig and was very happy to see power output back to normal at the correct IP level. This is a very satisfying experience and confidence builder for guys like us. I'm not a tech but with the advice and direction from guys on this board and Dick, the repair turned into more of a mechanical operation than electronic. The service manual is very helpful because it shows an X-ray view of the board so that you can see which resistors to tackle. On the 830S I believe it was R2-R5. You can also see that the 4 resistors are wired in parallel and why the 20 ohm resistors should test at 5 ohms.

So, as it has been said many times on this forum, if we wanna dance with these radios, we must learn to pay the fiddler... Since I did the cathode resistors, I swapped out the screen and driver caps and resistors, the HV caps and the 470 ohm resistor on the rectifier board. Piece of cake.

I believe I have ordered every repair part that Ken K4EAA sells for the 830S. All I have left to change out is the RL-1 relay and the final cage kit. Then my 830S should outlast me!

Hope this helps you get the bug to dig in and work on your rig. Best of luck.

Tom

Subject: [TS-520_820_530_830] TS-520S for parts or restore

  Good Morning and Happy New Year,
I have a 520S I had used for 160 M receiver that I no longer need. I have disconnected the HV from the PA tank and all tubes are removed but it is 90% complete. It would not take much to get back on air or would be a good rig for parts. I have no desire to repair it or use it any longer. If anyone is interested in it, shoot an Email my way off reflector. Otherwise it goes to the storage shed.
73, K5HFG
Don

Tom,

Whilst you have final cage open, look at the capacitor (C7) that sits between the two tubes at the top of the ceramic plate choke, this always ends up being cracked due to the continual heating from tubes.The inductor L1 (small green looks like resistor), at the bottom of the of the ceramic plate choke may be discoloured, this will then need to be replaced along with C8, which suffers when L1 burns up and also from the heat produced by the two tubes. Look at the large white cermaic plate choke and see if it has signs of darkening, if so, this will be due to incorrect loading of PA. Alll these parts can be bought from Ken, K4EAA, all will be rights size, wattage and will be correct type 1, RF caps at the right KV rating.

It is a fairly easy exercise and good to build confience and learn how these fine radios work. Report back if you need further assistance

73's

Dave

Ok ..here is what we have so far.....tube pin #1 to ground reads infinite ohms
all 4 R 2, R3, R4, R5 read 20 ohms
R 7 READS 111.5 SHOULD BE 100
R 8 READS 129 SHOULD BE 100 ALSO
BUT going back to the tube pin test it shows infinite and it was posted that if there is more than 6+ ohms they R 2, 3, 4,5 are bad.....but they show NO VISIBLE DAMAGE

They don't have to look bad to be bad. CHECK THE TRACES On the circuit board to make sure there is nothing lifted, cracked, or broken. Also check where the socket is soldered on. Use a BRIGHT light behind the board and look carefully for hairline cracks using a magnifying glass if your eyes are old and bad like mine.

The components might indeed be fine, but the connections between them and the tube socket may not be.

Dave,
just so I have this clear:
   You removed resistors 2 ,3 ,4 & 5, (all 20 ohm) from the final amplifier board and tested them, and got 20 ohms on each and every one? Interesting.
You further stated that measuring from Pin 1 of final amplifier tube you got infinity? Interesting.
Did you test from pin 1 of either final tube to ground with all four of the 20 ohm resistors in place?

I find it very confusing that pin 1of either final tube to ground reads infinity...but supposedly the resistors in question were measured at 20 ohms each. Therefor, if properly measured, as these resistors are wired in parallel, Ohms law dictates that there should be a nominal reading of 5 Ohms. The other 2 resistors you measured are out of spec, but currently are not a factor.

Dave
KG6SVF,

Yeah, that blue wire was a pain. Those soldered post wound wires are hard to salvage. Much easier to work on the board if you remove the blue wire from the post or the other end on the RF board though. I debated lifting the RF board to get at the blue wire there rather than disturb that post, but your call. Like I said before, I worked around it without having to remove it.

Forgot to mention, that if you look at Ken K4EAA RK-53 parts for this repair, you'll find a link there to an excellent set of photos that show the location of the resistors that need to be replaced.

You'll need a good Elmer ham buddy that has a few tools and test gear. I hope he is familiar with hybrids. Different world than solid state. Again, be sure to ground out those high voltage circuits in and around the cage.

Sounds like you don't have a way to test your cathode resistors. Mine looked perfect but they tested way high when measured on and off of the board. But you'll need to measure their resistance on the board to determine if they are indeed the problem. Should be 5 ohms, pin 4 to ground.

Techs here say that those cathode resistors pop or go high from abuse. My 830S has been in storage for the past 27 years and I certainly didn't abuse it in the 80's. Stuff happens though. But since I replaced all of these parts, I have cut IP back to around 200ma. My manual says I can go to 265ma but that's just nuts for the marginal additional power output. So now run about 80 watts on CW and 20 on PSK31 using an ALC negative bias circuit on SSB. See all the stuff you learn here? 6 months ago I had no idea what negative bias was nor its impact on the radio, much less build the circuit.

Go slow, think about what you are doing, be careful and don't be bashful about seeking step by step help here. There are so many highly qualified and patient guys here that will offer you all of the help you'll need. You'll be glad you posted with this group.

Hi all and Happy New Year!I always felt that the cooling of 2 x 6146B of TS-830s were not such as would be, in the long hours of rag-chewing! Hypochondriac in what has to do with the appearance of my transceivers(homebrew or otherwise) did not want in any way to vandalise* the TS-830s to secure the fan. I'd rather leave it as is! Nevertheless, where there is a will there's a way. The way you see in the pictures! By myself there was no way to get away with this chore so I enlist the big gun.With the invaluable help of my TRADING PARTNER (I do not say friend, not to "burn" him!) Apostolis SV1EDY, we found, we cut, puncture and lathed a piece of plexiglass to be used as adapter / flange between the fan and the chassis. Then, this piece was marked and drilled out the holes for attachment to the existing chassis and then marked and drilled to fix the fan. The air flow is outwards and actually blowing ...! From the gentle breeze of the previous with copper(!) impeller, to gale! By the way, I use the same fan to cool the 572B tube, of a self-modified KW600, 160m - 10m + WARC bands.I have upload a lot of photos at a file titled "cooling my TS-830s" 73Panos - SV3AUW / M0LPT

Yes, Dave, you have to lift one lead of each 20 ohm cathode resistor to accurately measure each individual resistor value. If you do not lift one lead of each resistor but you connect your ohm meter probe across only one of the four resistors, you will measure the "total" parallel resistance which will be approximately 5 ohms, not 20 ohms as you might think.

I have a video on my website where I talk about "parallel resistance". I recommend you view the video so you can see how parallel resistor values are measured, etc.

Go to my website:

www.w5rkl.com

then click on the "Videos" link at the top of the page. When the Videos page comes up, click on the /*Parallel Resistor Theory*/ link under "/*Introduction to Basic Ohms Law*/".

Overkill

I used my ts 830 for many years in RTTY . Reduced drive for 70 watts mark tone and let it go. Most of my operations were keyboard to keyboard but several half hour transmissions I reduced to 50 watts. For PSK you need to drop it down to 20 watts anyway. That radio had never needed new 6146 but after several years needed driver tube. Most harm is done by careless and slow tune-ups rather than normal SSB or CW operation.

All I did was bend the original fan blades a little (to make sure all was in alignment) and keep it lubed with light machine oil (also known as sewing machine oil here).

In reality, most of the cooling of the tubes is by radiation of infrared. Tubes are in a vacuum and only the tube pins and plate cap can conduct heat out. In fact high power glass tubes must have most air flow to the pins and plate cap so that they will not desolder themselves.

One answer is to dull the finish of the inside of the final housing or even use a little flat black oven paint to prevent the radiation from the Plates from reflecting back to the tubes.

It is always annoying to hear another station that sounds like a mobile with the window down and the driver having to shout over the wind noise! HiHi.

ac6tk, Jim

I am envious of your machine shop. I cut and drilled some Teflon rod stock by hand and made replacements for the old Nylon shaft couplers. They look a little "hokey" but should outlast the whole radio by a thousand years.

This is the greatest flaw I have found with the radio. They will all need shaft couplers for the band switch and load controls.

Your adapter plate is beautiful.

Jim

Hello, I wanted to share my Kenwood 820S ongoing story with you. I have been a ham since 1989 however I have never been on HF, other than CB back in the 80's. My background was VHF and Digital so for many years I stayed with what I know. Last winter I was bored and decided to upgrade to general. I download the app for my iPad and studied for the general and extra tests. Passed them both last winter. So now I decided to try HF. I bought a cheap 12 meter / 10 meter radio for the truck. It works well enough with an auto tuner and CB antenna.

I live in a condo so I was only going to listen. I found and bought a Yaesu FT-757gx and while I was getting it up and running I also found and bought a Kenwood 820S. The Yaesu works only after recapping the entire receive section of the radio.

The Kenwood is very clean at first look however the digital display did not turn on. I read the internet and found, like all of you know, the lack of soldier is the issue. I resolidered all the points on the bottom however that only worked for about two weeks. I then solidered the top of the board where the feed thought holes are. That worked for about a month, and then a power bump happened. I took it apart and resolidered all the resoldiers areas again…so far so good. I think it's the wire connectors themselves, I am thinking about removing the connectors and just direct connect all the wires. Thoughts?

I decided maybe I should try to talk with people; it is my right now that I am an extra to use these bands. I keyed the radio to tune it and it would not unkey. I pulled and cleaned the relays, now it unkeyed but the receive would not come back for sometimes minutes. Using the source http://www.hybridrestore.com/ http://www.hybridrestore.com/ I did replace the two relays with new and that fixed that issue; or did it. I found that I am only transmitting with about 10 watts. I replaced C7, C8 and L1 and now I have 50 watts http://www.hybridrestore.com/parts/#fcrk http://www.hybridrestore.com/parts/#fcrk however I expected 100. I then replaced the two 100 ohm grid resistors as when pulled measured 140 to 200 ohms. I tested the two larger 10 ohm resistors and they both measure 9.5 ohms so I did not replace them. I still only get about 55 watts at dead key (CW) on 20 meters. Maybe it's the tubes? Thoughts?

I have the Yaesu connected to a tuner into a G5RV jr on the condo attic running north and south

I have the Kenwood direct connected to a 20 meter dipole, inverted V that because of space is a W running east and west.

The Kenwood has now provided 20+ contacts on 20 meters with nothing but praise for how it sounds. The Yaesu; not so much. With both radios on the same band and frequency, the Kenwood hands down is a much better receiver.

Other then the lower than normal power issue, its was well worth the $200 for the radio +$40 (relays) +$20 resistors +time to buy and troubleshoot this radio.

Dave,
Mike is correct, but I usually don"t waste my time measuring each of the 20 ohm resistors...the solder pads can only take so much de-solder..and re-solder. With the final board in place and you measure from the places stated prior, and you get a value more than about 5.5 ohms, one or more cathode resistors are out of spec. The 5.5 ohm value is MY break point.I will replace all 4 of the 20 ohm cathode resistors, and since I'm already there, the 100 ohm screen resistors as well. Then I can measure the resistors totally out of circuit..and confirm that one or more were out of spec. This is just MY preference.

As you may have guessed, describing your problem is one of the most important steps. Measuring is the next, and then following through with the instruction(s) given. If for some reason you do not understand what is being conveyed to you...PLEASE ask for clarification. This group has many members from the "I'm just starting" to "nuclear reactor techs."
It's important to remember that were are trying to help who ever asks. That's why it's important to be as clear and concise as possible. Remote diagnosis is difficult if the parties are on different pages.
Also, remember to properly sign you posts.

50762. R7 on 530S smokes when tuning up 160 Meters

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-01-02 19:02:27 UTC
From: yahoo@...
Topic: 50762 Message: 50762

Apologies to the group if this has been brought up before...

Just getting back in into ham radio (first licenses in mid-70's) with a used TS-530S.

Did a field alignment and all but one band works fine.

When I tune up 1.8Mhz, and give it a bit of drive, the small 12K L7 Resistor (near L23) starts smoking.

This only happens on 160 transmit (receive is fine), and, none of the other bands are impacted this way.

Before I rip the lips off the RF board and get it out to remove the resistor, I checked across from the coil over to the resistor lead and got ~21K ohms.

The bandswitch seems to

I just can't seem to figure out why this is happening, and then I found these wonderful groups.

Can (a somewhat older or wiser) Elmer help me here?

Thanks in advance!

Tom:

Never seen this before. So when you attempt coil pack alignment and when adjusting L23 you can get some peaking in ALC indication as R7 begins to smoke?

I assume you mean R7 and not L7.

Are you positive it is R7 that is smoking and not R38 adjacent to it?

If it is R7 it is what they call a D-quing or Damping resistor. It is in shunt with C32 and L23 tank circuit. It is used to change the shape of the resonant frequency response curve of this 160 meter Driver LC circuit. It flattens and broadens it out. R7, C32, and L23 are all in parallel so the RF circ current splits between them. Roughly R7 is 12k ohms and C32 reactance and L23 reactance is approx 465 ohms. So the bulk of the RF current splits between C32 and L23 with very little in the R7 branch. There is approx 65 RF volts in the Driver plate circuit so the max power that R7 would have to dissipate is 65 x 65 / 12000 or approx 0.35 watts or about 1/3 watt. If R7 was bad would expect it to go higher in resistance and would see less RF current unless L23 has open winding or has bad solder connection. If that happened then have two parallel paths but still bulk of current would flow in capacitive branch. Just hard to believe that R7 could see so much RF current that it would get so hot it would smoke.

If you pull board suggest you pull C32 and L23 and measure them and also look for carbon tracks. C32 should be approx 180pf and L23 should be approx 39uhy.

I would be very interested in what you find.

Terry K9TW

50764. TS-520 AGC problem..??

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-01-03 16:54:08 UTC
From: Peter Koch
Topic: 50764 Message: 50764

Dear Group,

Being the proud owner of an otherwise fine and well-functioning TS-520, I want to ask you some advise concerning an annoying problem which I believe may relate to the AGC.

When powering up the radio, 1) the S-meter immediately goes to full reading, and 2) there is no sound from the receiver. After a few seconds, the S-meter slowly goes to zero (or whatever signal strength there is on the ant.-input --- RF-gain is full clockwise) and the hiss gradually appears in the loudspeaker. The AGC switch is in SLOW position. The same happens then the switch is in FAST position, but the time constant is somewhat less. Normally, from a solid-state receiver I would expect the sound to appear in the loudspeaker "immediately" when powering on the radio, and similarly the S-meter to have instantaneously correct reading.

Now, if that was the only problem, I think I could live with it, but exactly the same behaviour is seen when switching from TX to RX mode. When the AGC is in SLOW position, the time constant is so high that my counterpart has started transmitting way before I'm able to hear anything (and the S-meter has settled to correct reading). This problem is alleviated a bit when operating the AGC in FAST position, but still not sufficient to conduct a QSO with normal TX/RX rate.

I have been studying the schematic and it seems to me that the AGC basically is located around Q6 on the IF-board. On the output on this feedback circuit there is a 1uF cap, C27. Could it possibly be this capacitor which is malfunctioning, or do you believe that I should look for the problem somewhere else.

Any hint would be very much appreciated -- thanks.

Best 73
Peter, OZ1LFI

Easy to overlook this but just to be sure check the very thin copper wire running from the top of the plate choke to the final tube connector bar. Could be broken if someone wasn't careful working in the final compartment. I know - happened to me. This will definitely cause a pop when it happens and will negate output.

From: Mike W5RKL
Topic: 50767 Message: 50767

I have a very nice Allied A-2516 ham band with WWV receiver for sale. Trio Kenwood marketed the same receiver as the JR500S. The front panel has similar appearance to the Trio Kenwood TS-510S transceiver. A transmitter that matched the JR500S/A-2516, appeared to have been considered but never materialized.

I have a video on my website's "For Sale" link that shows the receiver in operation receiving WWV. The missing screw shown in the video on the rear panel's audio's 500 ohm terminal is no longer missing. If interested, contact me off group, my call at yahoo dot com.

Hello, I have a MFJ-299 I use on another radio, the microphone has a selector for up to three radios. I was wondering if anyone in the group is using a MFJ-299 on a TS-820S or this vintage Kenwood Radio.

I have a MC-50 desk mic that is wonderful but I am look at installing a digital voice recorder "in" the MFJ and was hoping not to have to move the DVR back and forth by using one mic for both radios.

If your have one working, what output on the mic are you using, and can you provide the wiring you came up with please.

Hi Darrell,

You should use output B of your MFJ299 and follow
the manual that comes with the unit and your
Kenwood manual. If you don't have either you can
download the Kenwood manual from the files
section and MFJ have the manual online.

You said something about using the mic for both
radios - I don't understand what that means but
here are the connections that would suit any Kenwood with a 4 pin mic plug.

Kenwood Pin 1 to MFJ299 Pin 6 - Mic
Kenwood Pin 2 to MFJ299 Pin 4 - PTT
Kenwood Pin 3 to MFJ299 Pin 3 - PTT Ground
Kenwood Pin 4 to MFJ299 Pin 5 - Mic Ground

Don't be tempted to join the PTT & Mic grounds
together and make sure you don't switch them over
or you could get hum on your TX audio.

Regards

Lou

Hi Lou, thank you for the quick reply. I was thinking since my other unit is a Yaesu. I can switch from Yaesu output to the Kenwood Output and leave both radios plugged in. This would allow me to free up desk space and also allow me to build only one DVR in the mic for use with both radios. This may work but then again it may not. It all depends on if MFJ insulted each output. I'll pull the prints and review. My main concern was that the mic worked with the TS-820s radio.There is a swap coming up on the 11th. I'm going to pick up a cable, mic plug, DVR parts, ect. I'll report back when the project is complete what I came up with.

Thank You,
Darrell

50775. No Output and Burning up Cathode Resistors.

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-01-03 22:45:43 UTC
From: nedavis49015@...
Topic: 50775 Message: 50775

I have a TS-520SE and a friend of mine has a TS-820s and we share the same problems.

Both radios had crispy cathode resistors. I replaced those in both radios. I tested the 820S, and it worked well.Bot rigs have proper screen voltages. I returned it to my friend and he usede it on 40 and 20 meters with out a hitch. He then went to 10 meters and in the process of tuning, there was a flash and no output.

We now have the same problem with no drive and both radios exhibit a pegged meter when switch is in ALC position and the carrier pot is at zero. I plan to repair my 520 first if I can remedy this quirk. (I have already replaced my cathode resistors but I get the same pegged meter response and no output.

Any advice will be greatly appreciated.

What does S meter do on initial power on if you have the PL-259 disconnected from the SO-239 connector or the antenna switch in the dummy load position? What you describe sounds normal with an antenna connected to the radio.

Slow return to Rx mode from Tx mode may be something entirely different. May be due to RL-1 aux relay and not getting AGC bus voltage transferred back from ALC bus due to a dirty contact. Aux relay is not easy to access for cleaning as it is under the VOX board on top left rear of chassis. Sometimes easier to also remove the left side adjustment pots mounting plate as well as the VOX board to access this relay for removal and cleaning and reinstall of its hold down wire bail.

Tom

Resistors are easy to get off Ebay or Mouser or myriad of sources. Just need to replace any carbon composition with metal film. Physical size will be much smaller today and that is ok.

I havent looked at the cap but suspect it would have to be a Temp Coefficient cap and harder to find today. Mouser and others have limited supply of NPO and COG caps.

The inductor would most likely have to be harvested from a TS530 or TS830 RF board and that presents a challenge. Can also be rewound if you have a steady hand. Easiest would be to harvest one from a TS530 or TS830 RF board or a parts rig. I made educated guess about 39uhy value. Would have to remove and measure with LCR bridge. If you need that I can do that as I have couple of harvest RF boards here that I use in repair of customer radios. I am not in the parts selling business.

Other thing to do would be to find a TS830S RF board and take opportunity to rebuild the bandswitch before installing it. I would never just swap out boards without taking hard look at the all the bandswitch contacts. When you can find an RF board looking at minimum of $100 for one and cant assume it has good L41, good Q1 or good bandswitch contacts. Dick Housden W0NTA is one of the best at rebuilding these RF boards and testing them after the rebuild.

Again I dont know why R7 is smoking. Very rare for C32 and/or L23 to go open. Logic tells us it has to be seeing very high current (either RF or DC). Have to ask self how is that possible? That brings you to three parallel paths. If C32 and L23 were both open then R7 would be the load on the Plate circuit of the Driver tube. If we assume that the Driver tube has approx 8 watts dc input power (297v x 27ma) and 30% efficiency as Class A amp then we would expect to see approx 8 x 0.30 = 2.4 watts output drive. If R7 is exposed to 2.4 watts and it is a 1/2 watt resistor I cant imagine it getting so hot that it would smoke in the short key down time it takes to peak the drive.

Now the other thing that R7 does see is the Driver tube anode voltage (approx 300 vdc) so it could be seeing DC current. Normally resistors go high in value. If R7 somehow has gone very low in value then perhaps it is the DC current that is causing it to smoke. Would have to have a bad C39 .01uf cap to complete the dc path to ground thru R9 1K ohm resistor. You might want to take a look at C39 and R9 back by VC-3 air variable cap close to the PA cage. If R7 is still 12k and C39 is shorted then it would see approx I = 300/13k = 23ma. Power = .023 x .023 x 13k = 6.9 watts. So now might see some smoke with 1/2 watt resistor dissipating 7 watts?

I am just thinking out loud here.

Terry K9TW

Hi to everyone, this is my first post and asking for some advice, help, comments, suggestions, etc.

I am new to amateur radio, so my knowledge is VERY limited.... I purchased a used TS-820S abt 4 months ago... It is physically in almost mint condition and free of smoke environment... All of the switched and controls appears to be working smoothly and as designed.... I purchased the radio prematurely I suppose, as I wanted to listen to the bands while studying for my FCC license.... After I received my license, I tuned up the rig as per the instruction manual, and even got on the air a few times with 100 watts output.

Here is my present situation, As I was tuning up the rig a week or so ago, I noticed the "meter" dropped in output to abt 50 watts.... But I then "re-peaked" the plate and load controls and got back abt 100 watts output again.... Everything seemed fine for a few days, but yesterday, I attempted to tune up the rig, got almost 100 watts output, then suddenly, the meter dropped to abt 15 to 20 watts output....

I hesitate in trying to tune the rig again, for fear of making matters worse.... Would anyone know of, or have experienced this type of condition before ??? Again, any help or suggestions will be most appreciated.

thank you all

Carl,
Several areas to check
   Check the "resting" HV(high voltage) by putting meter selector switch in "HV" and flip the send/receive switch to send...it should read approx 850 or more volts. After the rig is tuned up for max power , recheck the HV. This sag in HV should not be more than 20% of the first reading. When you first tune up and before the power fall off, what is the HV(high voltage) reading? You should see 750V or more indicated on the front panel meter. If the value is approx 50% ...say 400V or so then at least 1 HV capacitor is shot. These measurements are not exact and may vary.

Next, with the rig tuned up, put meter selector switch in Ip. and put radio in "send," watch the front panel meter..if the value slowly falls off...then the final amplifier tube(s) are possibly going bad.
Next: tune up radio. Turn OFF "SG" switch on rear of radio, mode switch to "CW", meter switch to "ALC," key radio and advance "CAR" control...you should be able to get FSD(full scale deflection) with the "CAR" control turned up to about the 9 to 11 o'clock position...and see if the meter needle drops off...if it does drop off...then the 12by7a driver tube is going bad.

FOR SALE: 2 year old Kenwood TS-520S with matching 520 external VFO w/cable and matching TS520 Speaker. Internal PS, runs off of 125vac.

Equipment was purchased in 1977 and put in the closet when owner went SK in 1979. Equipment had plastic dust covers on all, all this time. Almost perfect.

Does have 2 years' worth of use, plus a little plastic rubbing. Leather stitched handle looks brand new. Operates great on all bands, 100 watts output. Does not have WARC bands.

Original Owner's manual, Original Sales receipts from Nov 1977. Original Log book 1977-1979.

Absolutely gorgeous! Should not go to a new ham as "first radio". Would like to sell complete for $450. Shipping extra.

OR trade for a later model Kenwood or ICOM; 440SAT, 450SAT, 735. Equipment is to support a public Middle School HAM Club.

Photos available. In Aiken SC area. Will be at the Greenwood SC Hamfest Jan 10 2015.

Kent

HI Joe,,, thank you much for ur reply...Putting the switch to HV position, resting, the meter reads 750 volts, in send position... 14.065 into dummy load....

Step #2, After my "tune up" and switch in HV position, reading on meter is 800 volts.... There was no power fall off... meter was steady...

Step #3. switch in IP position, meter reads steady at just under 700 volts...

Step #4, SG switch is off, Mode switch in CW position, and meter in alc position, advanced the Car knob to
three o"clock position and have full scale,,, no meter drop off at all....

After tune up, my watt meter shows just a tad under 100 volts output....

I hope I have followed your instructions... I redid the procedure twice.... Do you think there could be an intermitting problem somewhere.... maybe clean contacts, etc. ????

Although when I tuned up for this procedure, the meter did not deflect or show a decrease in power, as before.... Thanks much for your input and time, Joe... carl

Carl,

When you set the TS-820 meter switch to IP and key the transmitter, the meter displays the final amplifier's cathode current NOT high voltage.

Thanks Darrell and Terry for your individual feedback. Please find below the additional info that you asked for. 1) Yes, when switching OFF the AGC, the Tx/Rx issue vanishes. In FAST mode the S-meter is pegging and then drops relatively fast when I release the PPT, and the loudspeaker sound returns equally fast. In SLOW mode the meter reaches approx. S9, and on PTT release the meter drops to S3 within 3-4 seconds at which point the loudspeaker sound also returns. 2) Disconnecting the antenna or substituting it with a dummy load has no effect on the behaviour during power on. Meter still pegging and then dropping. No sound until after some seconds depending on OFF/FAST/SLOW mode If this info can help you narrow down any potential AGC problem, then I'd be grateful. Otherwise I'll try Terry's suggestion on the RL-1 aux relay.

Thanks, Peter, OZ1LFI

Hi Peter, I turned off my TS-820s and let it sit for about 5 minutes. When I turn it on the meter pegged and then went to noise level. I think that is normal.

As for the slow TX / RX I would start by cleaning or replacing the two relays. One is visible the other in in a little metal box :).

I cleaned both of mine but they didn't work any better.... I replaced both of mine as my TX to RX was taking 1 to 30 seconds.

50791. Hybrid Net Update (December 4, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-01-05 01:09:01 UTC
From: Mark Gilger
Topic: 50791 Message: 50791

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by me, WB0IQK. There
were 28 stations checking in under good band conditions.

We had the following number of radios checking in.

3 running TS-520(x)
2 running TS-530(x)
6 running TS-820(x)
10 running TS-830S
0 running TS-511
0 running TS-511
0 running 599 twins

I was running my TS-830s & Drake L4B amplifier.

The Sunday net was run by me, WB0IQK. There were
26 stations checking in under fair band
conditions. He had the following number of radios checking in.

5 running TS-520(x)
3 running TS-530(x)
1 running TS-820(x)
5 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-940S + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins
November 2014, Saturday☐s net total 142, Sunday☐s total = 88
December 2014, Saturday☐s net total 92, Sunday☐s total = 86
January 2015, Saturday☐s net total 28, Sunday☐s total = 26 (Month to date)

Topic: 50792 Message: 50792

Greetings, I am the proud owner of a Kenwood TS-520, and a newby to HF.
the ppl on the local "teck net" said I should not use an external antenna tuner with my dipole antenna since the built in final tuning process does all you need.
is this true. is there nothing to be gained by using a tuner.
when I just tune the radio on a frequency, I sometimes get as bad as 1.8:1 without the tuner, but if I put the tuner inline I can get the swr down to 1.1:1.
does it matter?
thanks for any help and for this awesome group.

They are right, if you can tune it to 3:1 or less, the radio tank circuits will do the work for you without an extra tuner (with all of the attendant insertion losses from the extra connections, losses in the coils and air-variable capacitors, and so on).

If you're able to get 1.8:1 without it, you are probably actually transferring more power to the radiated signal than you would be at 1.1:1 WITH the tuner in the circuit.

I have a tuner which I only use as a balanced feedline input instead of coaxial cable. The radio only has coax output, and my antenna feed is ladder line. That's the only reason I bother with having a tuner on my bench. (But that's just me, and everyone knows I'm weird.)

What I recommend most to you is that you get an antenna handbook, the ARRL one or about any of the other offerings, or even search for information online. LOTS of stuff about antennas on the web, some sites better than others, of course so you must look at each one and see if it is worth anything. But that is so with ANY topic on the internet, not just ham radio information.

One "search term" you might want to use is

SWR Resonance Myth

That should get you some information on the real difference between "VSWR," "impedance," and "antenna resonant frequency."

What it boils down to is that the lowest SWR is NOT ALWAYS at the resonant frequency of an antenna.

Depending on the design of the antenna and feed system (dipole, off-center-fed dipole, loaded whip, whatever) ar the resonant frequency the antenna might present an impedance of 25 ohms (2:1 SWR) or some other fraction. If the antenna is truly resonant at the frequency you are transmitting, with an impedance of 25 ohms using that example, and you "tweak" the tank circuit for 1.1:1 SWR, you will be LOSING power.

Probably a lot of it.

I think antennas are the one thing MOST ignored by the new ham, and the ONE thing over which you have the most control, and which has the greatest effect on your signal. Not everyone has the geld or the space or the desire for a set of monstrous beams a hundred feet in the air,

but almost anyone can buy or scavenge some wire or pieces of aluminum and bits of hardware to make a really good antenna system. You can even build your own balanced feedline (ladder line) out of scrap wire and some plastic electric-fence parts ($3 a bag of 100 at the local tractor supply near me) if high-quality coaxial cable is too dear or doesn't give you the performance you would like.

Lots of options. You don't even need to spend a lot of cash on an electronic antenna analyzer. There are freeware antenna modeling programs that will tell you pretty closely how a proposed antenna will perform, if you will learn how to use them.

A lamp-cord dipole is a good start. I think you're already probably on the right track. But look into perhaps adding to your antenna repertoire, it's quite a satisfying thing to make something new and novel, and try it out on the air. Well, I find it to be so, anyway.

If you have an SWR of 1.8:1 the radio will work just fine with that.I would read the SWR over a range of frequencies from below to above the band if possible and plot them on a piece of graph paper to get a look at where the antenna is resonating. then you can trim or lengthen it to the preferred frequency you expect to do most of your operating on. You don't really need a tuner if you can fix an antenna with high sWR !~

50795. Statistics for the Hybrid Net

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-01-05 14:19:16 UTC
From: Mark Gilger
Topic: 50795 Message: 50795

Anyone that's checked into the nets knows that I
like keeping track of what Hybrid radio your
running. I thought it might be fun to tabulate
up how many of what radio checked into the net for the past 12 months.

On average I'd say we get between 20-25 check-ins on a net.

The Saturday net shows more TS-830's checked in
than any other radio's, while the Sunday net
shows the favorite radio is the TS-520(x)
models. Interesting to see how many of the old
520's are still in regular use. There are several
people working on their 599 twins, so we should
be hearing more out of them this year.

We have had 5 different stations checking in with
their new TS-990's and I have to say the older
radio's sound as good as the brand new models.

Saturday Net @ 7.235 :
TS-520 = 97
TS-530 = 92
TS-820 = 102
TS-830 = 109
TS-510 = 0
TS-511 = 0
R599/T599 = 4

Sunday Net @ 14.316 :
TS-520 = 103
TS-530 = 43
TS-820 = 60
TS-830 = 93
TS-510 = 2
TS-511 = 1
R599/T599 = 5

The net started it's existence on November 1st,
2011. Here are the yearly check-in totals for the past 3 years.

Nov. 2011 ☐ Oct. 2012 Saturday total 754 check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

73's,
Mark, WB0IQK

Richard,

May I direct your attention to the following ARRL website link that discusses what a tuner actually does and how to adjust a tuner for lowest SWR..

Antenna Tuner Operation http://www.arrl.org/antenna-tuner-operation

Antenna Tuner Operation http://www.arrl.org/antenna-tuner-operation The American Radio Relay League (ARRL) is the national association for amateur radio, connecting hams around the U.S. with news, information and resources.

View on www.arrl.org http://www.arrl.org/antenna-tuner-operation
Preview by Yahoo

Notice that the ARRL webpage stated that all tuners may not have the same control labels. For example, Drake labels the TRANSMITTER control as "Reactive Tuning" and the ANTENNA control is labeled as RESISTIVE TUNING. The "Inductor" has taps that are wired to the center band switch. A Kenwood AT130 tuner has the TRANSMITTER control labeled "R TUNE" and the "ANTENNA" control labeled "X TUNE". The inductor taps are selected based on the BAND switch. A Johnson "Transmatch" has the TRANSMITTER control labeled "TUNING" and the ANTENNA control labeled "MATCH". The inductor taps are through the band switch control. You just have to understand that even though the control have different names they perform the same function.

You should also note the ARRL webpage appears to assume you are operating a modern no tuning required transceiver. Since you are using a KW hybrid that requires tuning the transmitter, you should tune the transmitter into a 50 ohm dummy load FIRST. If you do not have a 50 ohm dummy load you should obtain one. MFJ has a 300 watt dry 50 ohm dummy load for $39 (see MFJ website for further details). Once you have the transmitter tuned up properly into the 50 ohm dummy load, switch the transmitter output from the dummy load to the tuner's input. During the time you are adjusting the tuner for lowest SWR, do NOT touch/readjust the transmitter DRIVE, PLATE, and LOAD controls since they are already adjusted for maximum power output into a 50 ohm impedance load. Adjust ONLY the tuner controls for lowest SWR. Once you have achieved lowest SWR, you are ready to operate.

Hi Richard, very good question. I don't have a direct answer for you, however I can pass a long what I have learn. I asked the same question a few months back on a SWAN user group and got reply's from always to never.

If you can tune the radio without exceeding the plate current of 225ma with a good current dip the tune is good. You can't measure the SWR because you cannot get the meter between the TUNE circuit and the PA board. That's what I believe to be true. I'm sure others might have other opinions about this.

If you install a tuner then you can measure the SWR and you also can tune up antennas that are more out of the proper impendence range. In other words my belief is the radio can tune a 20 meter dipole to be used on 20/15/12/10 with little or no issues. If you want to use the house siding or a fence for an antenna then you be use something that has a wider input range to then balance that to the radio circuit.

I am new to the Kenwood radio line myself but in the last 3 months I have been using a Kenwood TS-820s on a 20 meter dipole - with no tuner - stapled in the attic of my condo with contacts all over the US.

50799. Final Cage Purpose?

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-01-05 19:08:10 UTC
From: roberteleazer@...
Topic: 50799 Message: 50799

The TS-520 I am working to repair came without the removable cover for the cage that encloses the final amplifier section. I am building a new cover for the cage, and I'm painting the cover both to improve its appearance and reduce the chance of corrosion - the replacement is made out of aluminum.

The question: Is the the final amp cage designed primarily to reduces the chances of shock during maintenance, to improve cooling for the final amp by ensuring that air is drawn over the finals, or does it provide some kind of RF shielding?

The issue is whether I have to ensure good electrical contact for the cage cover to the rest of the cage. If I paint both sides of the cover, there will not be much, if any, electrical contact.

Thanks!

Robert

That's normal to have 300VDC on the RF Unit's "DRV" terminal. The Rectifier Unit's 300A B+ voltage is applied to the RF Unit's "300" terminal which connects to the 12BY7 driver tube plate, through L9, L7, and L1 to "DP" and finally to pin 7 (PLATE/ANODE) of the 12BY7 driver tube. "DP" also connects directly to the RF Unit's "DRV" terminal which is why you see +300VDC on the RF Unit's DRV terminal. You can see this on the TS-520 main schematic.

If you follow the heavy black wire from the RF Unit's DRV terminal to the Final Unit's "DRV" terminal you will find capacitor C1, 100pfd, inter-stage coupling capacitor. The sole purpose of C1 is to block the flow of DC voltage but allow the RF signal (has an AC sine wave component) signal to flow through C1 and be applied to the final tube grids.

Topic: 50799 Message: 50803

You don't have to paint the aluminum cover. A replacement cover can be made out of perforated aluminum found at most hardware stores. The top cover provides safety to prevent you from touching the +920VDC on the final tube plates as well as RF shielding. Perforated aluminum provides all that plus a lot of holes for ventilation and it's easy to cut and bend to shape. Cost is cheap if you buy remnants, smaller pieces left from cutting a large piece. I made a top cover for my Heathkit Apache TX-1 final amplifier using perforated aluminum, no need to drill any holes. You can cut it with regular scissors, no need to buy or use a pair of tin snips.

Topic: 50799 Message: 50804

Ok! So I'm an old fogey!
But although this group sets out to help hybrid users (of which I am one) and does so very successfully
it is just plain scary that someone would make a new enclosure for a final amplifier with, apparently, not even the understanding of the most basic science. Based on safety considerations alone.

The answer is of course for all the reasons given so far-
RF shielding, safety from high voltages and protection for the final tubes. But also there has to be a compromise between enclosure and air flow. Kenwood finals are not especially efficient and hot air has to RISE out of the enclosure freely while cool air is blown in.
My 820S had a very poor fan, which was replaced with a 12 volt computer type run off the rectified 12 volt heater supply. This more than doubles the air flow while reducing fan noise.
But the 820S outer case can also cause problems, the top cover in its original form reduces the airflow.
It may not be original but mine has some perforated aluminium inserted in a new hole above the finals.
Drops the temperature there by at least 5/10 degrees C.
But as I have always found a bit of basic science (very basic) goes a long way in any technical pursuit.

Mike:

That's a good idea that had not occurred to me.

But I own an airplane and I'm building another one, as a consequence have multiple pieces of "scrap" aluminum available in thicknesses ranging from .030 to 0.25 as well as at least 5 different tin snips. So I selected a couple of pieces, trimmed them appropriately and drilled lots of holes in them.

I have only painted one side and I'll leave the other side bare.

Thanks!

Robert

You're shocked that anyone would ask a question? What else would we be doing here?

I have multiple examples of tube type radio transmitters that do not have any kind of a cage over the finals.

And I am well acquainted with the "basic science."

Hi folks....Just a quick question from a no brainer, (ME)...I am anticipating purchasing the add on VFO for my 520s..
My plan is to utilize this during "split" dx operation...I will be using the add on as the transmitting frequency and the VFO in the radio for the receiving VFO..Easy enough I guess... Not sure of the settings yet between both units but will read the VFO manual I have downloaded..(I thank Ron WB4HFN for said manual)
I also have the DG5(KV6O) Emulator hooked up...Will the emulator see both VFO frequencies????(via switch positions on the VFO and radio?)I know I will learn "in the trenches" but a little help from the "group" would be greatly appreciated..Thanks, ahead of time.

Well Robert, I am a vintage radio specialist and run a small business restoring old radios and communication gear for museums etc. But the last transmitter I ever had or built without shielding was a copy of a 1928 QST design I built for a museum display. Ever since TV came in it has been even more important to shield finals. If not to save the operator from electrocution then to stop TVI!!

Having a 100 watts + of RF floating around loose is NOT a good idea. As an example my trusty old TX used a TT21 final in a 1 cubic foot aluminium box, which also contained its 5763 driver stage. With no outer box, even in a good reception area TVI was present despite all the usual precautions/ Also of course the class AB2 final ran with 1,000 volts on the plate, so safety was a definite consideration. Final tubes dangling in mid air sounds downright 1920's to me.

Mike,

Using the VFO-520 is very easy. The VFO-520's FUNCTION switch is where the VFOs are selected.

To use the VFO-520 for transmit and the TS-520's internal VFO for receive you simply select "XMIT" on the VFO-520 and the VFO-520 now controls the transmit frequency and the TS-520's internal VFO controls receive.

To use the VFO-520 for receive and the tS-520's internal VFO for transmit you simply select "REC" on the VFO-520 and the VFO-520 now controls receive and the TS-520's internal VFO controls transmit.

To use the VFO-520 for both xmit and rec, you simply select REC/XMIT and the VFO-520 controls both transmit and receive.

To use the TS-520s internal VFO for both xmit and rec you select "OFF" on the VFO-520 and the TS-520 internal VFO now controls both xmit and rec.

If you can't find a VFO-520 then you can use the VFO-820 remote VFO, The opposite is true, you can use a VFO-520 with a TS-820. Both VFOs are the same except for cosmetic differences in the cabinet's and front panels. No mods/changes are required, even the cable is the same.

Robert:

You are exactly correct. Anyone who uses self-annoited titles and drills holes in a KW hybrid cabinet and adds high volume fans clearly demonstrates a lack of understanding of "basic science".

Yes the PA cage provides a safety barrier, but the primary purpose of the PA cage is not a personal safety barrier from accidental contact with high voltage. If that was the main goal then we would see metal shielding over the exposed final board, over the exposed HV rectifier board, over the exposed solder terminals on the power transformer secondary and primary windings, and over the exposed HV filter capacitor solder terminals.

We are ham operators and not appliance operators. We dont affix "no user serviceable parts inside" labels on our gear. Mfg of commercial gear are required to install barriers and interlocks. Those hams and trained technicians who homebrew and routinely service are schooled and experienced with evaluating safety risks and employing safe work practices to manage those risks.

If you grew up in the hobby in the 40s, 50s, and 60s you would have seen the development of shield boxes, faraday shields, and PA cages. Look at a 1946, 1956, and 1966 ARRL handbook and you will see there were commonly no PA cages on any of the CW Class C transmitters just as there were none in most of the commercial and kit CW transmitters. Isolation between PA input and output was done by placing the grid circuits below chassis deck and the plate circuits above deck. Removal of the cabinet covers on these transmitters exposed the ham operator to high voltages at multiple locations including the anodes of the final tubes. As mentioned he was trained to deal with this or learned the hard way.

Not until we see the advent of the inclusion of a VFO and Radio Telephony in this Class C transmitter box did we start to see shield boxes and PA cages routinely appear in transmitters. Three purposes----- isolation of PA input and output, preventing RF into the Speech amplifier and VFO, and most importantly and the No 1 reason was prevention and reduction of HARMONIC LEAKAGE.

We had VHF television in those days and the harmonics that cannot be 100% eliminated from the transmitter output could wreak havoc with those VHF channels. Look at the Handbook chapters on TVI prevention and you will read about metal and screenwire shielding and lead treatment with chokes, by-pass caps, and feed thru capacitors. No real problem today as virtually no one watches off air VHF television. When is last time you saw anyone on this forum ask about the need to install a Low Pass Filter in the coax lead from their Hybrid? I cant remember last time I have seen or heard a discussion about Harmonic reduction or TVI. About only way to ensure you have a harmonic problem is to load your 80 meter dipole on 160 meters and pump KW into it. Every once in awhile will run across a CW QSO on low end of 80 phone band and if you tune to 160 you will find the culprit!

The other primary reason we have a PA cage is we have evolved to operating a SSB transmitter and receiver in small confined common box. We call it a Transceiver. We have the PA cage as I said primarily to reduce Harmonic Leakage, but we also have to isolate the

RF from the other circuits in the box. Why is there a metal shield can over the Ant TR relay? It is to isolate the PA stage input and output so we dont have an oscillator. It is to ensure we dont have RF into the Speech amp and other circuits.

Now ask yourself a "basic science" question. How are the 6146 tubes cooled and do the tube manufacturers require auxiliary cooling? If the tubes are run without exceeding the maximum ratings (see the Tube Data Sheets for ICAS service) the only required cooling is via Natural Convection. We wont go into Basic Thermodynamics here and insult or bore anyone. The addition of the PA cage impedes or restricts the efficiency of the natural convection. This is the only reason that KW added the quiet low CFM fan.

In theory you can run without this homebrew pa cage cover you are fabbing now as not very likely you will have any neighbors bothered by harmonic radiation. I would say a better reason to make and install one is to help with the input/output isolation, limit RF into the auxiliary circuits, and yes to prevent you from accidentally dropping something into or contacting the HV that is present.

I continue to be bemused at how Stupid the KW Engineers were!

Robert anytime anyone schools you that has a title like Specialist, Guru, or Doctor in the absence of a delete key you would be well advised to summarily dismiss.

Terry K9TW

Wow, thank you soooooooo much Mike (W5RKL) You answered my question, superbly. I was worried that I may be buying a "Pig in a poke", equipment wise..... I just wanted a third party tell me that is is a relatively simple function to use the remote VFO for split operations... I am relieved....(DX is tough and getting tougher)

My quest for info on this is fairly simple.I tried to drive my Clipperton amp. with my new ts590 and all I could get out was max 750watts... No mater how I tuned, EVERYTHING.....
I took a chance and hooked up my old 520s to the amp. With amp. at Low power setting I am getting 900 watts OUT..... I checked it with several SWR/wattmeters to make sure I wasn't getting lied to.... I followed that up with a run at high power....That Clipperton (and I)was enjoying 1250 watts OUT an no pain or strain..... Wonderful.

I wasn't sure if my input to the amp. was sufficient but now I KNOW it was underfed with the ts590.... My old 520s is a dream come true..... I have an 830 (My favorite) sitting right next to the 520s....
I LOVE the old Hybrids..... Please keep up with your great work,(Group). I am an avid member....I hope to have my turn at bat and help other members with some feedback in future..

Thanks ,again, Mike(W5RKL) and other members.... With your help, this radio, hobby is ,even more pleasurable.

Best of 73's and HAPPY NEW YEAR to all
Mike (KD2DYY)

Mike (KD2DYY), your reply stated the following:
/*
"*//*Follow up... The last line of Mike's(W5RKL) reply.... You stated I could use the VFO-520s on a TS-820.....Can I ,also, use the VFO on my Ts830???????.... Of course , the necessary,rewiring of cable connections..*//*"*/

Yes the VFO-520 will work with a TS-820 (no rewiring of the cable or changes to the VFO and transceiver are required!!!) Will the VFO-520 work with the TS-830? I don't know where you got the idea the VFO-520 will work with a TS-830 by simply rewiring the VFO-520 cable is simply not true!!

The VFO-520 AND the VFO-820, are both interchangeable with and compatible with the TS-520 and TS-820 series transceivers ONLY and they both have an output frequency range from 5.000Mhz to 5.500Mhz, same as the internal VFOs in the TS-520 and TS-820 models.

The TS-530 and TS-830 internal VFOs as well as the remote VFO-230 and VFO-240 have a "different" output tuning frequency range, 5.400Mhz to 6.100Mhz.

This TS-530S was fully restored by W0NTA, purchased by a Ham who didn't keep it long, then sold to me. It's in near mint condition and works as it should. Narrow (1.8KHz) SSB selectivity installed. I am selling the rig and original manual. No microphone or other accessories. It's possible that the driver, and or the finals are a little weak. I can get 90 - 100 Watts out on all bands. I don't think I could tell this rig from a brand new one. My shack is a non-smoking shack and rig does not smell of smoke at all. This rig is definitely "collector quality". Selling because I got an opportunity to upgrade to a similar condition, W0NTA restored TS-830S and jumped at it. $325 plus actual shipping cost (professionally packed and insured at my local "Box N Go"... I estimate that to be between $40 - $50 depending on your location). Price is firm. No trades. Serious buyers only. CONUS only. USPMO. Posting to this list first. Thanks! WD9F / Woody fghester@yahoo.com

Mike (KD2DYY),
As to driving your amp with the TS-590S, I found a similar phenomenon driving my solid-state Ameritron ALS-600 amp. Sometimes the amp output with the 590S would be 400-500 watts, but I would get full amp output power using my 820S. What I think was going on was that the 590S was “de-tuned” into the amplifier input on some frequencies and the 590S was “folding back” instead of feeding at full power. The 590S meter SWR would be high on transmission, so what I did, with the amp in standby, was to hit the 590S AT (autotuner) button to tune the 590S into the amp, then I’d see full output on the amp when running. Seemed to work, but others in the group may have a better theory.

I tune both my hybrids into a dummy load before sending to the amp.

By the way, I use a 2db attenuator (A5DX Phil Salas) between my transceivers and the amp. The ALS-600 only needs 65-75 max watts for full output anyway and I want to avoid overdriving the amp, particularly with the older rigs (I have an 820S and an 830S).
I have been very happy using the ALS-600 with the hybrids (after rigging up or buying the appropriate amp keying cables). I do use the ALC with all rigs and the ALS-600.

I imagine you’d not want the 2db pad with the Clipperton, since 100W is likely needed for full output, but thought the info might be useful for those who may be using the hybrids with a solid state amp, as I do. The AD5X unit works very well, especially with the 12V relay that bypasses the pad when the amp is off and I want to run barefoot.

Subject: [TS-520_820_530_830] 520s-VFO.

Hi folks....Just a quick question from a no brainer, (ME)...I am anticipating purchasing the add on VFO for my 520s..
My plan is to utilize this during "split" dx operation...I will be using the add on as the transmitting frequency and the VFO in the radio for the receiving VFO..Easy enough I guess... Not sure of the settings yet between both units but will read the VFO manual I have downloaded..(I thank Ron WB4HFN for said manual)
I also have the DG5(KV6O) Emulator hooked up...Will the emulator see both VFO frequencies????(via switch positions on the VFO and radio?)I know I will learn "in the trenches" but a little help from the "group" would be greatly appreciated..Thanks, ahead of time.

Mike (KD2DYY)

There is no 120/240VAC primary voltage level switch on the TS-530S rear panel as seen on the TS-520 and TS-820 rear panels.

The primary AC voltage wiring change from 120VAC to 240VAC must be done manually, see page 27 in the TS-530S manual. The fuse must also be changed from 6 amp to 4 amp.

Jo De, I recommend you download the operator and service manuals for your TS-530. You can find them on my website:

www.w5rkl.com

Simply click on the Manuals, Docs, and Mods link at the top of the page then scroll down to the TS-530 listing and click on the appropriate manual.

I mean no disrespect but this is another one of those reoccurring common sense operator issues that could have been solved rather quickly if the owner/operator would have spent time reading the operator's manual. If the operator manual was not included with the sale of the transceiver then downloading the manual and spend time reading and studying the manual before you attempt to operate your transceiver!

Well unfortunately for your argument, my contention is based on real experience and real measurements.
Fortunately, though retired I have a pretty fully equipped electronics laboratory at my disposal and was able to make actual air and surface temperature measurements. For those who still wonder, just take a look at the crude construction of the original Kenwood 820 fan. The Wright brothers would have been horrified! (They designed the first efficient propellers too).
The air flow is doubled, with less use of energy and the lifetime of the final tubes is increased.
Perhaps the case area over the finals is not quite "original" or as pretty, but it works very well.
BTW if the reference is to my post, what titles exactly did I claim?
I've just had 50 years of working as a technical officer and technician in scientific research and at the local University.
In that time by fitting fan cooling to some tube equipment we had I was able to reduce failure rates by at least 10 times.
For future reference, as any hot air balloonist will tell you, HOT AIR RISES. It is less dense.
Its called convection.

> Robert:
>
>
> You are exactly correct. Anyone who uses self-annoited titles and drills holes in a KW hybrid cabinet and adds high volume fans clearly demonstrates a lack of understanding of "basic science".
>
> Yes the PA cage provides a safety barrier, but the primary purpose of the PA cage is not a personal safety barrier from accidental contact with high voltage. If that was the main goal then we would see metal shielding over the exposed final board, over the exposed HV rectifier board, over the exposed solder terminals on the power transformer secondary and primary windings, and over the exposed HV filter capacitor solder terminals.
>
> We are ham operators and not appliance operators. We dont affix "no user serviceable parts inside" labels on our gear. Mfg of commercial gear are required to install barriers and interlocks. Those hams and trained technicians who homebrew and routinely service are schooled and experienced with evaluating safety risks and employing safe work practices to manage those risks.
>
> If you grew up in the hobby in the 40s, 50s, and 60s you would have seen the development of shield boxes, faraday shields, and PA cages. Look at a 1946, 1956, and 1966 ARRL handbook and you will see there were commonly no PA cages on any of the CW Class C transmitters just as there were none in most of the commercial and kit CW transmitters. Isolation between PA input and output was done by placing the grid circuits below chassis deck and the plate circuits above deck. Removal of the cabinet covers on these transmitters exposed the ham operator to high voltages at multiple locations including the anodes of the final tubes. As mentioned he was trained to deal with this or learned the hard way.
>
> Not until we see the advent of the inclusion of a VFO and Radio Telephony in this Class C transmitter box did we start to see shield boxes and PA cages routinely appear in transmitters. Three purposes----- isolation of PA input and output, preventing RF into the Speech amplifier and VFO, and most importantly and the No 1 reason was prevention and reduction of HARMONIC LEAKAGE.
>
> We had VHF television in those days and the harmonics that cannot be 100% eliminated from the transmitter output could wreak havoc with those VHF channels. Look at the Handbook chapters on TVI prevention and you will read about metal and screenwire shielding and lead treatment with chokes, by-pass caps, and feed thru capacitors. No real problem today as

virtually no one watches off air VHF television. When is last time you saw anyone on this forum ask about the need to install a Low Pass Filter in the coax lead from their Hybrid? I cant remember last time I have seen or heard a discussion about Harmonic reduction or TVI. About only way to ensure you have a harmonic problem is to load your 80 meter dipole on 160 meters and pump KW into it. Every once in awhile will run across a CW QSO on low end of 80 phone band and if you tune to 160 you will find the culprit!
>
> The other primary reason we have a PA cage is we have evolved to operating a SSB transmitter and receiver in small confined common box. We call it a Transceiver. We have the PA cage as I said primarily to reduce Harmonic Leakage, but we also have to isolate the RF from the other circuits in the box. Why is there a metal shield can over the Ant TR relay? It is to isolate the PA stage input and output so we dont have an oscillator. It is to ensure we dont have RF into the Speech amp and other circuits.
>
> Now ask yourself a "basic science" question. How are the 6146 tubes cooled and do the tube manufacturers require auxiliary cooling? If the tubes are run without exceeding the maximum ratings (see the Tube Data Sheets for ICAS service) the only required cooling is via Natural Convection. We wont go into Basic Thermodynamics here and insult or bore anyone. The addition of the PA cage impedes or restricts the efficiency of the natural convection. This is the only reason that KW added the quiet low CFM fan.
>
> In theory you can run without this homebrew pa cage cover you are fabbing now as not very likely you will have any neighbors bothered by harmonic radiation. I would say a better reason to make and install one is to help with the input/output isolation, limit RF into the auxiliary circuits, and yes to prevent you from accidentally dropping something into or contacting the HV that is present.
>
> I continue to be bemused at how Stupid the KW Engineers were!

FYI, Perhaps "shocked" was putting it a bit strongly. My main concern was the safety of the user and the potential hazards to his (expensive) finals through airflow restriction. I am sure an aviator is pretty familiar with airflow!
But the way I have survived a couple of 1,000 volt DC shocks in my youth and it gives me a VERY healthy respect for high voltages. BTW I must admit that I wasn't impressed by the "openness"' of the 900 volt supply in the Kenwood. My old home brew rig had all the ht parts within a separate enclosed chassis and a dedicated meter able to read ALL the final tubes operating voltages and currents, including screen, plate and grid current as well as screen and plate voltages.

Yes the VFO-120 will work with the TS-530 and TS-830 because the VFO-120 frequency tuning range is from 5.500Mhz to 6.000Mhz, same as the internal VFOs in the TS-530 and TS-830.

The VFO-120 remote VFO is found in the TS-130 service manual, includes schematic, wiring diagram, specifications, and parts list. If interested, the TS-130 operator and service manuals can be downloaded from my website's "Manuals, Docs, and Mods page link.

www.w5rkl.com http://www.w5rkl.com

Scroll down to the TS-130 listing and click on the operator's and service manual links, one at a time, and they will download to your computer. The VFO-120 is found on pages 43 and 44 in the TS-130 service manual.

Thanks for the add. VY1MAB-Mark QTH-Whitehorse, Yukon

Thanks to the member(s) who posted the pic/description of the shaft position after replacing the plastic band switch shaft coupler. It was a huge help!

Just had my 1st QSO on the old girl. Got it and the AT-230 for my birthday. I had been drooling over it for a couple of months and now its mine.

Needed a small bit of TLC. Coupler, solder repair on one tube cap lead and a little contact cleaner and she fired right up!
3300km from Yukon to Nebraska. No amp, just barefoot. About 50W on the peaks. I have a amplifier cable on order, hopefully be here in a week or two.

Again, just wanted to say thanks for the add.

Problem solved with blowing fuse. Turned out to be a bad 6146b. I put another set in and a new 12by7a then managed to do a neutralize and now she's sweet as a nut on all bands. Now all it needs is a coat of new paint and new screws and then it's going to replace my TS 2000 at home.

NO I did not say that.

I was trying to explain the evolution of the PA shield cage and why we have one today in our KW hybrid radios. I went on to say that 6146B tubes do not require forced air cooling if operated within the maximum design parameters.You can validate that for yourself by reading RCA, GE, Sylvania and other manufacturers tube data sheets.

I mentioned also briefly how the kinetic energy of the electrons striking the plate produce heat and how that heat is radiated to the glass bulb and then removed by free air currents around the glass bulb (natural convection). I did not want to go into great length about Black body thermal emissivity.

This is how the 6146 finals are cooled in just about every 1960s commercial transmitter. Where is the cooling fan in the Johnson Viking II? Too many others to list.

I tried to explain that the addition of the PA cage which confines the two 6146 final tubes to a small enclosed space limits or impedes the flow of free air therefore that is why KW engineers speced a low speed, low CFM fan. A large volume of air movement is not required. Have to listen to far too many "hurricanes" on the bands as it is from mis-guided souls and poor operators.

Mr. Wright contends that the KW hybrid fan is not speced properly and claims to have made accurate bulb temperature measurements. He does not describe how he made those measurements without impacting the operating environment. Nor does he produce the results. Did he employ Temp Stick or Temp Laquer? Did he employ thermocouple junction, ice bath reference, and a potentiometer? Did he employ a contact pyrometer? Did he employ infra-red thermography?

The maximum bulb temperature is 260 degrees C or 500 degrees F. There isnt a KW hybrid rig in the fleet that exceeds that glass bulb temperature if operated at design. Softening of the bulb would occur at 750 degrees C which can happen if the tube experiences thermal run away either thru loss of operating bias or shorting of the inter-stage control grid coupling capacitor. KW engineers fixed the latter by adding a .01uf blocking capacitor in series with the 100pf coupling cap with the introduction of the TS820.

Mr. Wright speaks volumes about his scientific methods when he describes the TS820 cooling fan as looking like something off the Wright Brothers airplane.

I am directing my comments to all the new folks who come here for technically accurate direction and not voodoo or hamfisted direction. There is absolutely no reason to start drilling holes in your KW hybrid covers or had high volume cooling fans to your PA cage.

Before you do that ask your self one question:

If the KW hybrid PA is design flawed either in Loaded Q, LC ratio, or Cooling, why are there so many TS520 and TS820 rigs in service today still using the original final tubes? This is especially interesting as we know that it is not unusual for new and old owners alike to routinely not load in proper and conservative manner. Not to mention those who QRO

the radio.

We have beat this to death. The rigs are yours and you can modify to your hearts delight. It is the essence of the hobby. Unfortunately there are people tauting mods that are ill conceived and very poorly executed. I see plenty and just have to shake my head.

Mike:

Your purchase of the matching remote analog VFO is a very wise one. Not only will it facilitate split DX operation, but it will do some other things for you.

I see very many (50 plus per year) KW hybrids across my bench. One of the inspections I make when assessing the radios is the VFO action. It is very common for me to find a VFO knob that you would think is mounted on an eccentric, excessive axial and radial play, gear train drag, gear train noise, hard spots in the rotation, and even a few anti-backlash gears with no pre-load (broken springs or hamfisted adjustments).

I contact the owner to discuss options and common to get a response of " I hadnt noticed". Yikes-- is he brain dead? Probably not. Just no awareness or sensitivity. No sophistication, low quality standards or in some cases never owned a HF transceiver with a VFO so absolutely no point of reference as to what is good or normal operation. Certainly no shame if that is the case.

Here are some other reasons to buy the remote VFO and put it in service.

1. Typically the remote VFOs have far fewer turn to turn rotational cycles on them. Sometimes by an order of magnitude less. In short it may exhibit nearly factory new performance. What this means is you can limit the wear and preserve the remaining life of the internal VFO by routinely operating on the external VFO as the primary on some schedule. Load sharing.

2. It is a great troubleshooting aid. If you have abnormal long term drift is it due to the internal VFO or is it a regulated power supply problem? If the rig jumps in frequency or the PLL unlocks at points in the travel is it an internal VFO problem or a regulated power supply problem or other issue? Very easy to differentiate. If same problem presents on the remote VFO then you know the problem is not with the internal VFO.

All the controls in your KW hybrid are electro-mechanical which means they have bushings, bearings, gears etc. They are wearing out each time you use them. Most were high quality components and have lasted well beyond their economic design life. They are 35 plus years old. In short if you plan to keep your KW hybrid and troubleshoot and maintain it yourself then anytime you can acquire a part that has far fewer operational cycles on it I recommend you do so.

I would not be without a remote VFO. I have two VFO-240s remotes married to my two TS830s and a 520 and 820 remote VFO.

One caution about the 520 and 820 remotes and the internal VFO do not apply any force to L1 tank inductor if you are attempting to align the VFO. Its lead screw that moves the ferrite core in and out of the ceramic coil former is glued very securely and very easy to break off the slotted head of the screw. This is the voice of experience speaking here! Better to live with a little tracking error.

There's another positive aspect of using a remote VFO with a Kenwood hybrid... Less frequency drift and better stability. At least this has been my experience having owned them since 1978. Beyond the design characteristics and stability of the VFO, I presume this is due to the thermal differential as is the case with the transceiver's internal VFO within the same cabinet as the driver and PA.

Dave,

Will the VFO-120 work without mods to the VFO and/or the TS-830? Yes, no mods and not changes what so ever are required just plug it in and have fun!

The answer is by simply studying the external VFO connector box pin labels above item "6" EXT VFO (EXTERNAL VFO) CONNECTION on page 8 in the TS-130 operator's manual and the remote VFO socket wiring labels at the upper left corner of page 13 in the TS-830 operator's manual.

Both remote VFO sockets are wired AND labeled exactly the same. Therefore, the since the VFO-120 will work with the TS-130 then it stands to reason the VFO-120 will work "Plug and Play" with the TS-830!

Don:

Yes I think you are correct on what you have experienced and why it occurs. Usually the remote will have noticeably different warm up drift interval and somewhat better long term stability. As you note it is working in a different thermal environment which probably explains the performance differences.

I see a lot of internal analog VFOs and most meet or beat the published KW specs, but a few drift badly. I have tried loosening and re-tightening board mounting hardware and cleaning the pc boards with alcohol and most times it has no effect. I and the late Gordon N6WK went together on purchase of variety of temp compensating capacitors and tried different combinations without much success. We tried application of Q dope on the ceramic coil forms and applied glue to pot or bond several of the parallel path temp comp caps together to prevent motion and all the tricks we could think of. Every once in awhile get one that you just cant seem to tame.

I once bought a brand new TS-830 VFO in the KW packaging and with bill of lading etc. I was really excited until I installed it. It was of course free of axial and radial play and velvet smooth, but man did it drift. Very disappointing. The guy I bought it from said the Ham Dealer that sold him his brand new TS830 thru it in on the deal. I found out why!

That is what makes the huff-n-puff circuits so popular. I just had a TS530 here with a Cumbria X-lock module in it. I dont know if any better than K4DPKs stabilizer or not?

Hi

I opened the radio again.

1. Normal behaviour if I connect sig generator at the drain of Q1. Audio comes through. Also behaviour of RF gain is normal. The S meter shoots up when RF gain control is exercised. Does this mean AGC is working OK ?
2. L41 seems okay. No primary/secondary short
3. D2 also shows normal behaviour. Not short at least. About 500 Ohm resistance to ground.
4. Changed Q1 to 3N200
5. Still low sensitivity.
6. Voltages measured to ground.

D 12. 0 V
S 1.1 0 V
G1 0.7 V
G2 0.7 V

Obviously Q1 working parameters don't seem right.

What say guys .

Why arent you injecting at wiper of S1-3 or at Gate 1 of Q1? Very easy to access S1-3. Injecting at Drain of Q1 tells you nothing about Q1 or L41 which are the usual components that inadvertent transmit RF destroys.

If you have only 0.7vdc at Gate 2 either your AGC bus voltage is being pulled down or your voltmeter input Z is dragging it down. You should see approx 3.2vdc at Gate 2 using very high Z meter. With a 10 meg meter will see approx 2.4vdc to 2.6 vdc as previously discussed. If AGC bus (rail) was pulled down then IF amp chain wouldnt be working.

Very difficult to measure resistance of any inductor or transformer windings in circuit and have it mean anything other than perhaps not open circuited. The key is proper inductance and not so much dc resistance. Have to inject RF signal at TP-1 and then at S1-3 to test L41. Can do that in about 30 seconds. If receiver alive at S1-3 and not at TP-1 then L41 is bad. If not alive at S1-3 then typically bad Q1. D2 rarely fails and can test it by applying turn on bias across Driver tube cathode resistor.

Is the lead pin out the same for a 3N200 device and the original 3SK73 device? Easy to transpose leads and have unfunctional or damaged device.

Approx L41 parameters out of circuit are:

Primary Ohms = 0.26 ohms
Primary L = 0.86uhy (with slug flush with top of form)

Secondary Ohms = 1.01 ohms
Secondary L = 15.5uhy

I am sorry I mis-spoke.

I meant S1-2 wiper. Can inject at either red phenolic wafer, but S1-2 is probably little easier to access.

You can also inject at the "Small" plates of VC-1 air variable cap (top back solder lug) which is even easier spot to clip on.

I am looking for an AM Board for the TS-830M. I really need a good picture of the foil side of the board.
I have created a board, but due to the poor pictures from the service manual, it has a fault on it and I can't seem to find it. I have followed the schematic and everything seems to be where it should be, But still doesn't want to work. I have added all the extra items that the manual shows as the changes needed. Please advise.

I would suggest reviewing page 61 in the TS-830S service manual. Besides the AM board module, the mode switch has to be rewired, and the IF board has to be modified including adding the AM filters. Without the 6 KHz AM filters, the AM function is somewhat worthless. And, if you do get it all working, maximum power out in the AM mode will be about 25 watts carrier. Back in the 90's, I queried Kenwood Tech service about acquiring the AM board. The didn't stock them since the TS-830M was never sold in the U.S. However, he did quote me a price he had in his pricing list, but after adding in the additional AM filters, I decided to pass on the entire project as not very cost effective. With the money saved, I was able to head off to the local hamfest and buy two AM boatanchors. TS-830M's do come up for sale on Ebay on occasion.

If you want the thrill of Kenwood AM operation with a hybrid rig, find yourself a pair of Kenwood Twins, R-599D and T-599D. They both come with all the filters for AM/CW/SSB operation. Receiver even has a FM filter. Transmitter runs the same tube lineup as the TS-830 (12BY7 driving a pair of 6146B's). They can operate as separates or as a transceiver (with interconnecting cable). And, most importantly, they sound great on AM. On more then one occasion, when I was running my Twins, had trouble convincing the station on the other end that I wasn't running a plate modulated rig. They sound that good.

Hi Les,

The simple, one component TS-940 AM transmit audio mod comes from Jeff,
N8RWS:

> http://n8rws.com/940%20AM.htm

The new filter is readily available from Mouser:

http://www.mouser.com/ProductDetail/Murata-Electronics/CFWLA455KEFA-B0/?qs=9Q/tXio9PCRkD34
EIk/tmA==

And for the truly adventurous there's this:

http://www.amwindow.org/tech/htm/ts940s.htm

Given the good results yielded by the simple filter swap, I have not
incorporated these more ambitious mods into my 940, though it's tempting.

It will be interesting to hear what he says, but remember, you would still have to run something like 25-30 watts to keep within the duty cycle.

I would suggest reviewing page 61 in the TS-830S service manual. Besides the AM board module, the mode switch has to be rewired, and the IF board has to be modified including adding the AM filters. Without the 6 KHz AM filters, the AM function is somewhat worthless. And, if you do get it all working, maximum power out in the AM mode will be about 25 watts carrier. Back in the 90's, I queried Kenwood Tech service about acquiring the AM board. The didn't stock them since the TS-830M was never sold in the U.S. However, he did quote me a price he had in his pricing list, but after adding in the additional AM filters, I decided to pass on the entire project as not very cost effective. With the money saved, I was able to head off to the local hamfest and buy two AM boatanchors. TS-830M's do come up for sale on Ebay on occasion.

If you want the thrill of Kenwood AM operation with a hybrid rig, find yourself a pair of Kenwood Twins, R-599D and T-599D. They both come with all the filters for AM/CW/SSB operation. Receiver even has a FM filter. Transmitter runs the same tube lineup as the TS-830 (12BY7 driving a pair of 6146B's). They can operate as separates or as a transceiver (with interconnecting cable). And, most importantly, they sound great on AM. On more then one occasion, when I was running my Twins, had trouble convincing the station on the other end that I wasn't running a plate modulated rig. They sound that good.

Yes. One of my goals for the new year is to finally ll get the 30L-1 in line. Also, I'm curious re the mod. I ask, I learn. It's interesting to me that the TS-430, 440, the Kenwood twins, and now the 940 all have a rep for sounding vy gud on AM. My Drake TR-7 can run the mode but sounds lousy. I have communicated with Craig before and once brought something for him. He is very sharp and has a nice station, he used to have a swell site, I don't know if it is still up. (((73))) Les

So far, so good with a 50 watt carrier and relatively short 1 - 2 minute transmissions. The power supply and final amp heat sinks do not heat unduly and power remains constant.

I would really like to mate the 940 to an amp for AM use as you intend to do. I'd feel a bit better using the Kenwood as a 20 watt exciter. I'd also like to have about 150 watts of carrier to play with.

What amp do you gave, Les.

Hi folks. I wanted to address this to Dave (KC3CIP) off "group" in response to his suggestion using the 590 to drive my Dentron Clippertion amp but he did not have his address on QRZ.com site..At this risk of getting the moderator upset, just a quick response....Yes Dave I did try to auto tune the 590 while going for drive to the amp... No good.. In fact it was better without auto tune.I know the little 590 has rf output issues.... Anemic is the best description...Hence my turning to the Hybrid to give the amp a good kick in the pants of rf input power..The Clipperton flies with enough input excitement..... The lowly 520s does great job in that respect....I have just recieved a remote 520s VFO and will ,now, be able to do "splits" while working at dx..... Almost always the case these days . Especially with Navassa Island coming up. I'll need all the rf I can muster to bang into those,anticipated, pile ups. Hi Hi.Not to worry, I haven't given up on the 590. Beautiful radio! Modern is good but can't beat the old Hybrids for "carry the water" jobs...No finesse, just get-er-done duty....
Best of 73's to all who have helped me in this group......Great bunch even though I DO get yelled at once in awhile... I'll trying to smarten up.... Little more patience for me. PLEASE?

Mike (KD2DYY)

The following link may be of interest to you or those considering using linear amplifier's on AM.

http://www.w8ji.com/am_linear_amplifiers.htm

The link also discusses about AM power which should be of interest to you.

A lot of new hams have never operated AM. Some have been told or have been misled to believe that AM is "dead". This is not true. AM is still alive and doing quite well on HF. To operate AM, even on 10 meters, one has to be a General or Extra class, Technicians are not authorized to operate AM on the 10 meter band. AM on VHF and above is pretty much non-existent. There are some 6 meter AM stations around 50.4Mhz if I remember correctly but most AM operation is on HF.

Some frequencies you may find AM stations are 3.880Mhz, 3.885Mhz, 3.890Mhz, 7.160Mhz, 7.290Mhz, some on 20 and 15, and 29.0Mhz on 10. I operate AM on 10 using modified 11 meter transceivers with power outputs between 5 and 7 watts. The antenna is a simple inverted vee for 10. When 10 is open I have worked both coasts, Canada, and Europe with only 7 watts. You don't need a lot of power on 10. I modified a Johnson Messenger One 5 channel transceiver to operate on 29.0Mhz crystal control at 7 watts output. Cost was about $80 which included the transceiver, 2 crystals purchased from International Crystals in Oklahoma City, OK, and about 30 minutes of time to tune the transceiver to 29Mhz. If you want flexibility, one could buy and build an N3ZI DDS2 VFO, purchase a Johnson Messenger 223 transceiver, disconnect the crystal synthesizer, and use the DDS 2 VFO to drive the transceiver on 29.0Mhz. I have one of these and it works great at 5 watts on 10 AM using a non-amplified D-104 microphone.

Thanks very much for the great link, Mike. Very useful!

The first signals I ever heard on the ham bands -- from a homebrew one-tube regen receiver -- were amplitude modulated on the 75 meter phone band. Weeks later a ham neighbor invited me to sit in on an AM QSO in his shack, equipped with a magnificent National HRO receiver and matching "hi-fi" speaker. I've been partial to AM ever since and really enjoy chatting with or just listening to the guys in the 7.285 - 7.295 MHz AM window. My as yet unrealized dream is to build a proper plate modulated AM transmitter as described in an early 1950's ARRL or Edtiors & Engineers Handbook. Perhaps now that I am retired -- as of a couple of months ago -- I can devote some time and courage to such an ambitious project. It'll be a proper companion to my wonderful Hallicrafters SX-42.

In the meantime, I am certainly enjoying the limited but perfectly capable AM mode on my TS-940SAT.

73,

Craig

Hey, Mike.
No worries—sounds like things are working well with the 520S. There is a TS-590S Yahoo that might be helpful. I dropped out a while after joining because it seemed all they talked about was low output. I've had no issues with output power on my TS-590S and really like the radio. I did have the ALC mod done by Kenwood, but really hadn't noticed issues with ALC spikes on my ALS-600.

I'm operating my 830S on phone this morning during a 10M opening into Europe—lots of fun! 820S is on the bench for a tune up and a new band switch coupler. I have the VFO-820 to work split and it is a great addition. Enjoy your hybrid!

I just finished replacing the 10 ohm resistors in the final amp cathode circuits of my TS-520 and pulled the book out to find the pin voltages for the finals so that I could check that before proceeding with neutralization and then I saw it.

Is the plate voltage really 800 volts! I haven't thought about 6146s for a lot of years (I've been out of the game for about 26 years) but 800 VOLTS! That seemed very high to me!

So I looked up the datasheet for the 6146 online and it call for a max plate voltage of 400.

OK, what's the deal here? Does Kenwood know something that I don't?

Tom,

If you look at the RCA 6146B 8298A tube manual's data sheet for the 6146B operating in Class AB1 linear amplifier ICAS service the plate voltage is 750VDC at 225ma. Placing the amplifier in standby results in no current flowing in the tube resulting in no voltage drop in the plate circuit, hence much higher "no load" plate voltage.

Heathkit runs the same Class AB1 ICAS dual 6146A final amplifier in the HW-101 and SB-100 line of transceivers with a no load plate voltage of 825VDC in standby/receive!

50874. Kenwood Hybrid Net Update (January 11, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-01-11 20:01:11 UTC
From: Mark Gilger
Topic: 50874 Message: 50874

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm
The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by me, WB0IQK. There
were 32 stations checking in under good band conditions.

We had the following number of radios checking in.

5 running TS-520(x)
4 running TS-530(x)
6 running TS-820(x)
10 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
1 running TS-900 (N8CBX ☐ JAN)

I was running my Drake ☐C☐ line & Drake L4B amplifier.

The Sunday net was run by me, WB0IQK. There were
20 stations checking in under fair band
conditions. He had the following number of radios checking in.

5 running TS-520(x)
2 running TS-530(x)
0 running TS-820(x)
4 running TS-830S
1 running TS-510
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-940S + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940☐s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:

50876. Cathode resistors in the TS 530

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-01-12 13:25:36 UTC
From: bsa0791@...
Topic: 50876 Message: 50876

I have a TS 530 that is indicating high plate current. I feel it may be inaccurate. Will changing the the cathode resistors effect the plate current reading? How many cathode resistors and what is their location? Are they 10 ohm, 1 watt?

thank you Brian nc

50877. Re: [TS-520_820_530_830] Cathode resistors in the TS 530

Brian,

What do you mean by high plate current? Have you checked the bias pot setting in sideband (see the TS-530's operator's manual page 16 paragraph 4.3 TRANMISSION (I) for details)? It's quite possible the bias pot setting may have changed or the bias pot may be dirty.

50878. TS-520 Final Grid Resistors

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-01-12 16:55:25 UTC
From: roberteleazer@...
Topic: 50878 Message: 50878

Continuing with the repairs to the TS-520 I have been working on, I found that one of the 100 ohm final amp grid resistors, R6, was cracked. The measured value was also a bit low, so I elected to replace it.

I also decided to replace the other 100 ohm grid resistor, R5, as well; it was a bit discolored and you have to desolder one end to get to one end of R6 anyway.

Anyone know if this is a common problem or what it may indicate in terms of prior problems with the transceiver?

Thanks,

Robert
WB5WSV

From: Mike W5RKL
Topic: 50878 Message: 50879

Robert,

The resistors you are referring to are the final tube screen resistors, both 100 ohm 1/2 watt. You don't have to lift either lead to measure each resistor. The resistors you are referring to having to lift the lead are the final tube cathode resistors which are wired in parallel. The final tube screen resistors are wired in series with the tube socket pin 5 (screen). You simply connect the ohm meter leads across the resistor leads and read the resistance. You are thinking of the final tube cathode resistor which you have to lift one lead of the cathode resistor to measure each resistor (they are all wired in parallel).

The maximum 6146 final tube screen current, as provided by the manufacturer, RCA, GE, etc, is 12.5ma per tube, 25ma total (tubes are connected in parallel). A big mistake that can easily toast the screen resistors and permanently damage the 6146 tube(s) is if the plate caps are removed resulting in zero plate/anode voltage but normal screen voltage remains. When the plate caps are removed the screens become the plate(s) resulting in high current flowing in the screen circuit, easily damaging the tubes and the screen resistors. This is why it's so important to have a solid understanding of vacuum tube theory when servicing vacuum tube circuits.

Brian,
I agree with Mike-w5rkl. Check what he stated first.
A look at the schematic will show you that the "cathode resistors" are 20 ohm 1/2 watt, there are 4 of them wired in parallel. If you have an ohm meter, measure from pin 1 of either final tube to ground, You should have a nominal reading close to 5 ohms. If this makes no sense, study Ohms Law regarding parallel connected resistors. If the value obtained is greater that say about 5.5 ohms, I would replace all 4. The plate current that is displayed on the front panel meter is taken from the cathode resistor area.
The cathode resistors are located on the final amplifier board, X56-1380-00 on your 530S The board in question is what the final amplifier tubes are on. You can test the resistors from the bottom side of the board. You should do this with the rig UNPLUGED, and make sure all the HV(high voltage) is discharged from the HV capacitors. These pack a punch of about 850+ VDC...and will make you SK in a hurry. It appears that you are not familiar with these rigs..so I suggest that you try and locate someone that can help you with the locating of the resistors in question, and properly measuring them. Operators/owners manuals are available from numerous sources free of charge. Mike-w5rkl is one, and another is Gordon-n6wk. Both have a "dot com" after the call

I have a TS-820s that has been sitting around for a few years. When I power it up, the meter pegs and it doesn't matter what position the meter switch is in. I don't believe the transmitter is keyed. I am wondering if anybody would know enough about these to help me get started restoring this?

I have checked the T/R relay and it is clean, mic, car, af gain and rf gain are all the way down. mode is USB, no mic attached. band switch rod is good including couplers.
What else should I be looking at?

Scott,

First, you need to add a message signature to the end of your messages posted on this group.

Check the RF gain control, make sure it's rotated fully CW.

The meter switches are only enabled during transmit. In receive, the meter is an S Meter, nothing more.

Dave,
Are you referring to the small diameter copper wire? If so, not a big problem. As long as the rest of the windings look undamaged..ie: not burnt/black looking, you can repair it. It's odd that this happened. Having it break here indicates to me someone has been working around this area and may have broken it, and not known it .
Anyway, you're going to need soldering iron/gun, and some sort of adhesive...clear varnish or nail polish work good, BRIGHT LIGHT and MAGNIFICATION really help. Unwrap 1 turn or so, and then using the nail polish/varnish, apply it to the winding to stick it to the ceramic form, use your soldering iron/gun to heat the end of the small wire to remove the protective varnish...BE CAREFUL...it's easy to break, wrap it around one of the plate cap leads...and resolder it. Removing one or two turns of the winding, doesn't seem to make a difference in the big scheme of things. The value of the change probably can't be measured. I have used this method twice

Dave,
I looked at the pictures you sent to me. I have not seen this happen before. I can not remember all of what you are planing on replacing...but I think you are going to use k4eaa's final cage repair kit..is this right? I know you are working on the cathode resistors too. You must ask yourself,why did the cathode resistors pop? It is my experience that an internal fault in one or both final tubes causes most of them to go pop. This may have also caused the burning and severing of that small plate choke winding lead wire. The two capacitors and the very small RF choke ...(kinda looks like a small green resistor) may also have been damaged. Another item to check is the band switch coupler. It is at the end of the shaft that goes into the final cage. These crack at the set screw holes and can create havoc if the wafers on the RF board are out of sync with the one in the final cage. k4eaa"dot" com has a good picture of what you should inspect. Go to his home page...click on "repair examples" and you should now see the band switch coupler problem

It's tough at times when you get a rig second...third..or fourth hand..as the history is unclear and you have no idea what the previous owner(s) may have done to it. If you can, I would suggest that you obtain a known good pair of finals...and a known good driver. Testing in a tubes tester will not always ..if ever...indicate that the tube(s) will actually work in the real RF operating environment...many group members keep spares for diagnostic purposes. If the finals are at fault...and you put them back in...the cathode resistors will go pop again...and those small solder pads on the final board will only take so much before they lift off..and ruin you day.
Don't get discouraged...it's actually addictive to try and solve a problem and see it thorough to being fixed and operating. I have learned much from other group members, and I still am.

50892. MH4P Relay

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-01-13 19:40:33 UTC
From: Mike W5RKL
Topic: 50892 Message: 50892

I made a simple bottom view drawing of the Omron MH4P relay used in all models of the TS-520 as the Control and T/R relay. I uploaded this drawing to my website and click on Manuals, Docs, and Mods link. When the page comes up, scroll down to one of the 3 TS-520 model listings and click on the TS520 Relay link. The drawing is the same in all 3 TS-520 listings.

The drawing shows the relay's bottom view pin and each pin's number. The pin numbers stamped on the bottom of the relay are very small so you might need a magnifying glass to see them. The pin numbers start at the bottom right. Pin 1 is one half of the relay coil. Pins 2 and 3 are none existent and pin 4 is the other half of the relay coil. Pins 5 through 16 are the 4 separate SPDT relay switches inside the relay.

The BLACK lines show the relay terminal connections when the relay is NOT energized, ignore the RED lines.

The RED lines show the relay terminal connections when the relay IS energized, ignore the BLACK lines.

The MH4P relay located below the MARKER and VOX Unit boards is the Control relay. This relay controls quite a few circuits between RX and TX such as Bias voltage, RIT disable/enable, and other circuits. This relay can, if very dirty/corroded from sitting idle for long periods of time especially in a humid environment, can create a lot of problems. Although these relays have a plastic cover, they are NOT sealed. Therefore, moisture and dirt/dust can enter the relay, causing connection problems. This relay is NOT easy to get in and out. Care must be taken when extracting this relay. When cleaning the contacts, use care as the relay terminals can easily bend out of alignment. Dirt and corrosion can also enter into the relay socket. Therefore, while cleaning the relay terminals may help, you should also clean the relay socket as well. Apply contact cleaner to the relay terminals then insert/remove the relay a number of times to allow the "scrubbing" actions to remove dirt/dust/corrosion from the sockets. This is the same procedure you would use to clean tube sockets, wet the tube pins with contact cleaner and insert/remove the tubes a number of times.

I'll second the motion on 'be careful with these relays'. Just so happens that I just changed both of my TS-520S relays this morning. And I managed to bend over a pin when inserting the nastily located VOX Relay. Did not see it (can't see down in there), and did not feel anything odd when inserting it. But, as soon as I powered up, I heard the Antenna Relay pickup immediately, and the meter went full scale. So, I got to take that relay back out, straighten the bent pin, and then put it back in again. Managed to get it right on this second try. I probably took out the original factory relays. Now, hopefully I will quit experiencing intermittent signal drop out on my SSB transmissions. So far so good.

Mike,

The CAR control in both the TS-520 and TS-830 have the same affect on RF Output in TUNE and CW mode. The CAR control has no affect on RF output in sideband, the CAR control is disabled in USB or LSB.

The SB-200 has an RF driving power requirement of 100 watts. Why do you want to lower the driving power to your SB-200? See the SB-200 manual's "Specification" page. You do not need to lower power output from the TS-520 to drive the SB-200.

Greetings;

TS520SE;

Weak receive (barely hears at 10uv.; 14.200. Same on all bands.

Signal path from SO239 to "ant" test point is less than 2 ohms DC.

The 3SK45 (Q3) has been, sometime in the past, replaced with a FET marked "SK3187" (not an RCA SK number). Tried an ECG221 to no effect.

Voltages on the FET are correct (measured with Heathkit VTVM)..

There is no evidence of "screwdriver manipulation" (attempts at alignment) Tune is a bit broad, peak not as sharp as I would expect. Does peak well on transmit tuning.

Injection (50uv) at S1-2 wiper shows an increase, audio wise but no meter movement. Meter tracks RFGain control normaly. 6 Volt supply is within specs.

Q1.Q2 and Q3 on the R.F.Unit are in sockets. I have not seen this before

Thoughts and ideas will be appreciated.

Dave, W5WP

Dave,

Have you walked a simulated receive signal using the MARKER signal as the initial source of receive signal then, when no change occurs, switch to a signal generator applying the correct conversion signal frequencies at the appropriate points along the signal path? If not then I recommend you do that instead of measuring resistance and voltages, at least this point.

You will need a signal generator that can tune to 8.895Mhz and 3.395Mhz, no modulation is required, a frequency counter to ensure the signal generator's output frequency is correct, and a probe (I use a scope probe). Tune the VFO to zero on the dial with the MARKER turned ON and you hear the MARKER beat note, regardless how weak the beat note it.

Mike,

If you want to reduce power in sideband, go to my website and download the TS-520 QRP circuit pdf file.

W5RKL http://www.w5rkl.com

W5RKL http://www.w5rkl.com Welcome to my Amateur Radio website. 73 Mike W5RKL email: w5rkl@yahoo.com

View on www.w5rkl.com http://www.w5rkl.com
Preview by Yahoo

Click on the Manusl, Docs, and Mods link at the to of the page. When the page comes up scroll down to the TS-520s listing and click on the qrp link. You should tune the TS-520S up for maximum power output in TUNE and CW mode then use the qrp circuit to reduce power output in sideband mode. The pot shown in the circuit schematic is a 220K linear pot. When using this circuit with your 520, do not connect the amplifier's ALC connection, only the simple 9 volt battery and 220K linear pot to pin 6 (external ALC) and 4 (ground).

Check the RF ATTN switch, this switch can cause problems. Use a jumper to bypass the RF ATTN push button switch. Also cycle the X-verter and REC ANT switch, these switches are all in series with the antenna connector and the input to the RF UNIT board. If bypassing and cycling the switches does not improve the signal, connect a jumper from the MARKER UNIT's "MO" terminal (Marker Out) to the RF UNIT's "ANT" terminal. This test whether T6 and/or T7 are dragging the receive signal.

You can also use a signal generator, tuned to the appropriate frequency, to simulate a receive signal conversion such as the 8Mhz RIF signal that is produced at the receiver's first mixer (HET OSC mixing with the receive signal producing the 8Mhz RIF signal). If that doesn't show improvement at the appropriate points along the signal path then tune the generator to the 520's fixed IF frequency, 3.395Mhz and apply that signal to the appropriate points along the signal path.

At some point you will find where the signal improves significantly. When that point is found, move back to the previous point where the signal did not change and the stage ahead of that point is the source of loosing the signal. At that point you would start checking voltages to determine exactly what component has failed.

Also, don't discount the control relay which is located under the MARKER and VOX UNIT boards, top left rear on the chassis. This relay controls TX and RX switch such as bias voltage, RIT, receive muting etc.

Dave,

Measure the DC voltage at the IF Unit's "AGL" terminal with RF Gain set fully CW and no receive signal (MARKER turned OFF and antenna disconnected). The normal voltage at the AGL terminal should be +3VDC. If it's not, much lower then measure the DC voltage at the IF Unit's AGC terminal. If it's +3VDC then the problem is relay RL1-1 terminals are very dirty/corroded and/or the control relay socket is very dirty/corroded, dragging down the +3VDC bias to the IF Unit's AGL terminal.

Topic: 50899 Message: 50907

Mike;

Thanks for the input.

To summarize:

The attenuator switch was intermittent. Cleaning with a suitable contact cleaner resolved that problem, usually I guess caused by lack of use. The attenuator resistor and switch was tested by ohmmeter after the cleaning. Checking the path from the SO239 through to test point "ANT" indicated the switch was operating normally.

The voltage (AGL-AGC) is app. 3.2 volts, measured with a Heathkit VTVM which references against an HP-3456A. Bench scope is a Tektronix 465B.

The LO and mixers appear to be doing their jobs through the IF stages. Tuning is not an issue, sharp, and frequencies are accurate throughout the bands. Sideband offsets are what I would expect to see. S1-2 appears to be OK. More robust than in other, later models.

Since a signal injected past L-1 improves somewhat I am beginning to lean toward a defective L-1 on the RF unit . The replacement 3SK35s' should be here shortly and will use the result from replacing the current SK3187 as an input for the decision as to whennther to pursue this further or not. I assume the transformer falls under the heading of "unobtainium".

I am still curious about the socketed transistors: Not something I am used to seeing on transceivers. Is this normal in the SE or has someone reworked the board?

Thanks for your help.

Dave, W5WP

BTW: Signal source is an HP 8656B. All frequency generating and measuring equipment clocks (10MHz) are locked to 2 matrixed Trimble GPS receivers providing an accuracy (at 10 MHz) of between .01 and .02 PPB.

50908. TS-830S RF Board Cleaning

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-01-15 00:49:29 UTC
From: Steven Springer
Topic: 50908 Message: 50908

Hello to group. My 830 has been difficult to tune, but rocking the band switch a bit would get me a stable reading on the meter. Now those days are over and I can't get the ALC reading stable when in Tune and setting the drive control. The needle bobbles back and forth and I hear static in the speaker. Probably arcing in the band switch. So I removed the RF board and it is absolutely filthy with old grease, contact cleaner and dirt. Working on this board would be futile without giving it a good cleaning first. Any suggestions on cleaning this board such as immersing in soapy water or something like that?? I plan on removing the band switch wafers and going through them as W0NTA has posted on his site. Any suggestions would be appreciated.

Steve

Avoid water! Many say it's ok but I avoid it like a plague.

Use 99% Isopropyl Alcohol -it might be hard to find unless you have

a good medical supply near by. The 70% stuff you get at the big box store

is not preferred.

99% wash with a soft brush is my only method.

Mike

Well, there is a rather officious-sounding site:

http://engineeringlab.stores.yahoo.net/cleaning.html

which mentions "aqueous or semi-aqueous" cleaning solution for circuit board decontamination. It's fine, as far as it goes, but what it doesn't say is that an "aqueous cleaning solution" amounts to a sink of hot water with some Dawn dish soap in it, an the "semi-aqueous" one is equal amount of distilled water and isopropyl alcohol (the kind you get in the pint or so bottles in the grocers or drug store) to rinse and aid in the drying of the board.

I do not (unlike some others) recommend putting the board through a short cycle of an automatic dishwasher, but a sink, an old toothbrush or similar SOFT brush, and a rinse with alcohol and DISTILLED (de-ionized) water is usually very effective.

Caveat:

YOU MUST ALLOW SUFFICIENT TIME FOR DRYING

even if you use a heat source and accelerate it a bit. DO NOT over-heat the board, but you can move things along with some warm air across the wet board.

Your Mileage May Vary, and other opinions will appear. They are likely just as valid as mine and I would NOT argue the point. But this has worked for me for about thirty or forty years.

Steve,
As with everything else...people have their preferred method.I use "DAWN" dish washing soap. Do not use the stuff that goes into an automatic dishwasher...way too alkaline. I mix up about 1/4 to 1/3 cup of detergent in the kitchen sink. I use just enough warm water to make sure the air variables are covered and let the board soak for about 20 minutes. I have an old shaving brush that I use to clean around all the parts...watch that toroid coil! Rinse off with warm water...and I blow it off with canned air...and let it sit in front of one of the heating air ducts(about 18" away) of the house for a few hours. Others have put it in a "warm oven"....or set out in the sun...I have also used a hair dryer...to get a head start before the heat duct. This is a good time to inspect the foil side of the board at all the molex connectors and also the driver tube socket for questionable solder joints. After all this...I use some DeOxit on the wafer switch contacts as well as the wipers on the air variables, and the driver tube socket. Don't forget to apply 1 drop of light oil to the ball bearings of the air variables. You can either use a light oil or a light grease on the drive control shaft where it rests on the supports.

Make absolutely sure that the band switch knob, switch wafers, shaft, and switch in the final cage are properly aligned/oriented!!If in doubt...ask..an "out of sync" tank coil selector switch(S-22) in the final cage doesn't like a bunch of RF going to the wrong place. Now would be a good time to replace the band switch coupler too. Hybrid Restore, and K4eaa have good metal replacement ones.
Good luck.....

  Hello to group. My 830 has been difficult to tune, but rocking the band switch a bit would get me a stable reading on the meter. Now those days are over and I can't get the ALC reading stable when in Tune and setting the drive control. The needle bobbles back and forth and I hear static in the speaker. Probably arcing in the band switch. So I removed the RF board and it is absolutely filthy with old grease, contact cleaner and dirt. Working on this board would be futile without giving it a good cleaning first. Any suggestions on cleaning this board such as immersing in soapy water or something like that?? I plan on removing the band switch wafers and going through them as W0NTA has posted on his site. Any suggestions would be appreciated.

Steve K0SJS

50912. Display has "stuck" ones digit

Yahoo group: TS-520_820_530_830 (2015 — 2016)

From: va3vfo@...
Topic: 50912 Message: 50912

TS-820S display again. Everything else on display works; changes bands and frequency ok. Except that the "ones" Megahertz digit is stuck on "9"

Example (using random frequencies);
80 metres = 3.750 shows as 9.750
40 metres = 7.250 shows as 9.250
15 metres = 21.215 shows as 29.215
10 metres = 28.110 shows as 29.110
and naturally 29.500 shows as 29.500

all the usually cleaning, connector pin checks and re-flowing of counter boards was recently done (for earlier intermittent display). I have read and now can not find in the archives, info from a knowledgeable member who , for a similar problem, pointed to a few suspect IC's on the counter board.

If that of any other member has a specific suggestion for this "stuck' unit effect, I'd appreciate your help. I can try re-flowing again etc, but is it likely a specific area or IC on the boards?

thanks again.

Hello, when I was in high schooL (1984). I had a good at a small company that fixed POS systems for a department store. We would take every board and soak them in Isopropyl Alcohol, then hang to dry. Once dried, we would reseat all socketed chips and test the board. About 90% of the time that would be enough to fix them.

I think we sprayed something on the board to protect the copper traces but I don't remember what.

Hi Steve,

As an 830S owner and having just gone through what you are experiencing, thought I'd weigh in here too.

I saw all of the tips on cleaning the board and wafers. But, my understanding of the 830S band switch problem is that cleaning won't guarantee a fix.

First, you mentioned removing the wafer boards, I hope you have a Hakko or similar desoldering tool. Past experience with these vintage boards is that they will not take much abuse before lifting a pad or worse.

Second, the rivets that hold the contacts loosen with use and age resulting in a poor connection.

Don't mean to sound like a commercial message, but... Dick W0NTA fixed my board and it is perfect now. He does a LOT of these and has the procedures and fixes perfected. If I were you, I'd just send the board to him. You'll end up with a perfect RF board and it will stay that way for many more years.

Just sayin'...

Steve,
Cleaning the board is well and good, but I'd check out the band switch shaft coupler first. My 820S started to exhibit these symptoms and I found a crack in the original nylon coupler. Replacing with a K4EAA unit, cleaning the band switch in the final cage, and going over the control and transmit relays did the trick. You may need to rebuild some of the wafers on the RF unit and there are good sources on how to do that, but I'd do the coupler first and see.

I'll share my experience on my DG-1 unit to resolve a similar problem. I was getting a fixed offset on all bands (not the same spread as yours) and the display would track the VFO. I didn't see the issue with the "ones" digit. My problem turned out to be a bad decade counter (divider) chip, IC3. I replaced the original Toshiba TD3490BP with a Texas Instruments SN74LS90N and this produced correct readings. (Thanks again to Terry, K9TW for his guidance through this process).

The bad counter was causing the 1K clock signal to be 1.667 kHz and this was causing the offset. Suggest you measure the clock frequency with a counter or scope at the 1K pin on the counter mix board thru-connector. If you're getting 1 kHz, then my problem is not your problem. If the frequency is other than 1 kHz, then go back through the decade counter chips toward the oscillator checking pin 11 on each to see where the deviation occurs and that may be your culprit.

Hope this helps. It's not the end of my problems with the DG-1, though. Still working on why I'm getting an intermittent "fuzzy reading" on 21 mHz band and above most of the time. This unit is the bane of the otherwise excellent 820S!

Dave
KC3CIP

PS If anyone has any advice on my current problem (reads "twos and eights" on 21 mHz and above) I'd love to hear it! Dave

Steve,

Forgot to mention to check your VC1, 2 and 3 air caps for alignment. I had a ladder chain slip on VC3. Dick W0NTA, replaced the sprockets with new units with brass insets so slippage will never happen again.

Good Luck!

I got my 820 almost 2 years ago from my Uncle who was going into a nursing home, and I've learned a whole lot about them just by reading everybody's posts, so I sure appreciate the knowledge you guys have. I've been able to clean the interior of the radio and get several small problems taken care of due to your expertise.

Now I've run into an annoyance. I can try to transmit on just about any frequency I choose, but often now the radio may just go silent and the digital display will do some weird stuff. It's not the display problem that is prevalent with this radio because I've cleaned it - there's something weird going on with the Function switch.

When it starts acting weird, I can run the Function switch through its paces, and normally after turning it a few times, I can get it back to semi-normal and can transmit and receive... but then sometimes on the next transmission, it will again go back to a blank or erratic digital display and no sound.

Turning the Function switch, sometimes sternly, will get me back to the same deal. I can transmit and receive, but then it may go out again in a few minutes.

Any insight you guys can give me? Thanks as always for your help.

No Robert, I don't know who told you I had info on my website about conditioning tubes. I have information "about tubes", that includes tube manuals, data sheets for 6146s, 811As, 572Bs, etc but nothing about conditioning tubes.

The best way to test tubes is to use a DC Hit Pot tester. Terry, K9TW, has a link on his website that contains a White Paper on a DC Hi Pot tester.

www.k9tw.com

Click on the "How To Guides" link and click on the HI POT tester link.

Robert and others,

Go to K8CU's website

http://www.realhamradio.com/High_Voltage_Breakdown_Tester.htm

and read about his breakdown tester.

For those who may consider building a hi pot tester such as the one shown on Terry, K9TW, or K8CU webste, remember, the DC voltage is very high, on the order of 3KV and higher. If you have no experience working around DC voltage this high I recommend you do NOT consider building a hi pot tester on your own. Find someone who has experience working with high DC voltages to help you.

I want to thank everybody that responded to my problem,,
I ordered parts from Ken RESISTOR KIT FOR FINAL REPAIR and FINAL CAGE PARTIAL REPAIR KIT this past Saturday and had them on Monday when I got home from work, I just finished installing the cage kit.
2 of the 20 ohm 1/2 watt resisters were out of spec as were the screen resisters.
I just fired up the radio and have full 100 w of power, made a contact to Anchorage ANCHORAGE with a great report
Thanks again to one and all

Suggest you dump those final tubes. I would never use any 6146 finals again that have arced over (yes people do but it is a crap shoot). Also suggest you consider installing diode protection string across the cathode resistors.

Your radio has the R10 upgrade intended to prevent cathode potential rise during an open cathode event (without R10 the cathode will rise toward screen grid potential). R10 will protect your meter after the event, but wont prevent arc overs from blowing the cathode resistors open and your meter circuit seeing very high IR drop during the event (banging meter indicator violently against the peg).

A 3 silicon rectifier diode string from cathode to chassis ground should prevent cathode resistors from opening during a 6146 arc over event and protect the meter by limiting the IR drop to approx 2 vdc across the meter circuit. This will result in approx 0.45vdc across the meter and drive it full scale, but not with any force (normal full scale is 0.40vdc).

You can see the mod on Marks KW hybrid page on WB4HFN website.

Mike:

I guess I read part of a discussion between you and Terry on the Hipot test and thought you were referring to tube conditioning, which I have read of elsewhere.

The idea is that tubes that have not been powered up for an extended period (years) should have the filaments powered up for a few hours so to activate the "getter" and make sure that any air in the tube is absorbed prior to full B+ voltage being applied. This is to prevent arc overs.

A friend told me that he did not do the conditioning on some new 6146B's he put in a TS-820S and that they arced over. He says he is hoping he did not hurt the tubes too bad.

Some people say that some B+ should also be applied to the tube plate during conditioning, as in 250 VDC rather than 900 VDC. I was looking for some guidance on that aspect.

Thanks!

Robert

> referring to tube conditioning, which I have read of elsewhere.

http://w8ji.com/vacuum_tubes_and_vaccum_tube_failures.htm

Look at "Internal Anodes" in particular, but the entire article is WELL worth the reading. W8JI's site is full of good information.

Or you could go to the (really nasty, half-busted, loads the results with ads) Yahoo group page web site and try searching the archives for "gettering." Please give it a try, so as to save the whole thing repeating here on the mailing list for the <some ridiculous number>'th time.

The subject has been beaten silly here "a few times."

(But it seems to boil down to, "Gettering a 6146 ain't possible without special set-ups to get the extreme heat necessary. Just letting the filament run won't do much, it isn't hot enough in the right places." I believe is how it runs, to shorten it a bit.) But do please verify that in the archives. Lots of good reading and knowledge in there, along with some silliness and back-and-forths between old friends.

Try new tubes, once you get the resistors -- and add in those diodes for that protection modification. It's an easy mod and will save you loads of problems if they ever arc over again. It took more time to get the cover off and get into the thing than the mod itself, when I did it last summer.

(Now that I once again have a freq counter I can actually FINISH that job and see if my now UN-11-meter-modded 520SE will actually work again on 10 meters. It has been open on the bench since July or so, while I tried to resurrect the old freq counter. Nope. In the end, "Chips unavailable".... Or they cost more than a new freq counter.)

The Flash Getter has active Barium deposited on the glass envelope and it remains very re-active for the remaining life of the tube unless there is an atmospheric leak into the envelope (typically around the pin to glass seal area or anode lead exit). If that happens you will see the "mirrored " materials turn grey/white as the barium is "consumed" oxidizing the gasses contaminating the vacuum.

Some people believe that the natural out-gassing of the gasses entrained in the tube element metals and insulating support materials results in bubbles of these gasses forming and clinging to the metal and insulating supports instead of dispersing into the envelope. Therefore the active barium of the flash getter cannot readily act upon them.

I have never seen any scientific paper that supports or refutes this idea.

I am a former "cooker" of spare 6146 final tubes (using a DX-60) and my opinion is it doesnt help on tubes that have a flash getter, but it cannot hurt. You will have to try it for yourself. If you cook them and never experience an arc over then clearly you will have a much different opinion.

I have three 6146 finals here removed from customer rigs that have "grey/white" flash getter material. Two of them are GE tubes that had the anode cap twisted off the top of the tube cracking the glass where the anode lead exits. The other one I cannot see a point of atmospheric entry. It is common for the GE tubes to have broken anode cap glue so have to be very careful removing the anode caps. I have had some success in unsoldering the cap, removing the loose material, and applying small amount of JB Weld. After it cures resolder the anode lead wire.

Robert,

If you want to "cook" your 6146 final tubes in hopes eliminating the gas by some "gettering action" under filament voltage, then that's entirely up to you. I do not recommend following that method as there's insufficient evidence to prove it works.

Wes

You are correct numerous times this subject has been discussed on this reflector. Just as most all topics from what mic or what VFO will work, how to align shafts for BS coupler replacement, to how AGC and ALC works etc have repeatedly been asked and responded too. I suspect just about never a new topic is presented or very rarely. A natural phenomenon as new folks join. I have been asked off reflector numerous times to write a troubleshooting guide with expanded circuit descriptions. I suspect that 90% of it is already there in the archives. Maybe someone could produce a keyword searchable CD?

Anyway, Toms article is as you say very informative as is most of his work, but unfortunately does not address transmitting tubes with flash getters like our 6146 tubes.

He is talking about high power internal anode tubes like 3-500Z where the getter material (zirconium) is coated on the anode and must be heated to high temperature (anode will show color) to perform its function. Never want a 6146 anode to show any color. If you do likely will have a nice bright metallic spot or a hole at that spot when you are done. Interestingly almost always the anode metal holes and sucked in glass that I see is at the location of the mirrored getters. I wonder if that coating actually somewhat impedes the anode cooling that occurs via radiation and natural convection? This may account for why the original S2001A tubes have such longevity as the two getters in these tubes are located just below the phenolic base on one side directly adjacent to each other and can just barely see the flashed coating. No way for the "mirror" in this location to impede anode cooling. Just a thought?

The vacuum tube texts that I have read on the subject indicate that barium condensed on the inside of the glass envelope will react with oxygen, hydrogen, nitrogen, carbon dioxide, and carbon monoxide at room temperatures. Unless as I said in previous response you are in the camp that believes that some of the out-gassed molecules cling to the metals and insulating materials where the barium cannot readily act on them at room temperature. We have referred folks to You Tube videos in the past to watch how the flash getter is very rapidly consumed at room temperature if you cut the vacuum tube glass envelope sealing tit off and allow entry of atmosphere. Of course this is gross and rapid admission of gas molecules into the envelope.

I would love for Tom to write an article about flash gettered transmitting tubes. Perhaps he has and I missed it? Maybe someone could contact him and make the request. I wish he was a KW hybrid owner and member.

Dave,
Sorry to hear your cathode resistors failed But, I agree 100% with Terry-k9tw. If your cathode resistors have failed..it is most often causedby an internal fault of one or both finals. Do not use the final amp tubes again...you're asking for trouble...as you found out. The solder pads and traces will only stand so may "jobs"..before they lift off. The protection circuit Terry talks about is well worth installing...it's about $5 bucks or so

  Suggest you dump those final tubes. I would never use any 6146 finals again that have arced over (yes people do but it is a crap shoot). Also suggest you consider installing diode protection string across the cathode resistors.
Your radio has the R10 upgrade intended to prevent cathode potential rise during an open cathode event (without R10 the cathode will rise toward screen grid potential). R10 will protect your meter after the event, but wont prevent arc overs from blowing the cathode resistors open and your meter circuit seeing very high IR drop during the event (banging meter indicator violently against the peg).
A 3 silicon rectifier diode string from cathode to chassis ground should prevent cathode resistors from opening during a 6146 arc over event and protect the meter by limiting the IR drop to approx 2 vdc across the meter circuit. This will result in approx 0.45vdc across the meter and drive it full scale, but not with any force (normal full scale is 0.40vdc).
You can see the mod on Marks KW hybrid page on WB4HFN website.

This is response to request from Mike (K3MG) About anyone having a DG-5 display for sale...Two issues to ponder..... The DG-5 has shown many instances of failure over the years and they fetch some
big dollars to buy. Everybody wants one of those....There is a guy who does sell a DG-5 after market unit... He wants some good money for it as well.....OR.....
You might consider what I did.... If you are handy with soldering techniques and can follow easy directions, you might want to build your own....DG5 simulator..Go to KV6O web page and look what Stephan Leander designed...It uses a Arduino Microprocessor
board.... It' s GREAT..... I love mine.... I do have an offset to frequency call out but knowing that (It is stable amount)I take that into consideration and I can nail the frequency within .1kc.... Stephen is working on a calibration mod. for future design but it is ,quite, usable as is..... He has the Arduino code for this project on his web site as well....Good luck, Mike, and enjoy the Kenwood Hybrid..... I have the 520s and the 830s.. Both wonderful....

best of 73's..... Mike (KD2DYY)

Dave/Joe:

Ken K4EAA and I are good friends and on the cathode meter shunt resistors serving as fuses he and I agree to disagree so I doubt he will be offering protection mod kit of parts anytime soon.

If you are in the camp that KW designed them to be fuses and the fuse action is not the result of "accidental" engineering then you wont want to install the diode string across them. Purely your choice. Think about it and ask some other folks for their experience and basis for their actions and any recommendations.

I am not a mod person so it was hard for me to reach for this fix, but as Joe mentions I got tired of the unsolder/resolder cycles, removal/install of cabinet screws, and the unanticipated down time. Couple that with panel meter stress or destruction and I had simply had enough.

I discussed this problem with Tom Rauch W8JI and he helped me with the diode string and the glitch resistor and I borrowed the screen grid MOV idea from Ian White G3SEK of Tetrode Boards. You could also place a transient suppressor on the FG lead, but not very often will see an arc over from the anode to the control grid. That is really good as it could reach back to the ALC amp, theTIF amp, the Bias voltage pot and the -C supply. The TS530 added just such a device and no other protection which makes no sense, but it was not included in the TS830 design.

50948. SM 230 and ts 830 pairing?

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-01-16 23:54:31 UTC
From: David Drown
Topic: 50948 Message: 50948

I have a well cared for ts 830 "station" I have had since 1982. All components except the SM 220. I recently.obtained an SM 230 from an estate sale. Can I use this SM 230 with the 830? If so, I need advice as to how to connect the 230 to the 830. I am currently learning the ropes with my ts 990 which I have had for a year and one half. However, I still love my 830 as much as I did in 1982. Would appreciate any suggestions.

Thanks,

Dave

Mark,

Do you know when the forum will be held? I have a buddy (K9TF who was in the shack last Saturday during the 40m Kenwood Net) who is insisting I go this year.

Joe N9JR

,

If your coming to Dayton this year, keep in mind I would like you to give a talk on the arch over problem at the Kenwood Forum.

David,

The SM-230 has an input center frequency of 8.830Mhz which is stated in the SM-230 manual's specification page. This matches the TS-830 first IF frequency.

The TS-830's first IF frequency is 8.830Mhz which is the input frequency to the first 8Mhz crystal filter.

The SM-230 has an "IF IN" socket on the back panel (see paragraph 4.2 "REAR PANEL" in the SM-230 operator's manual.

The TS-830 will require a modification to add an IF OUT socket and connection to that socket from the 8.830Mhz first IF at the input to the 8.830Mhz crystal filter in order to connect the TS-830 to the SM-230.

It appears you do not have the electronic knowledge and skills to perform the IF OUT addition to your TS-830. Therefore, I recommend you find a local ham who has the knowledge and skills to perform this modification to your TS-830.

If you do not have the TS-830 operator and service manuals as well as the SM-230 operator manuals, then I recommend you obtain them before you attempt to make the connections between the SM-230 and your TS-830.

IF OUT 1 on the back of the TS-830S is an 8.83 MHz output (it's used with the SM-220/BS-8) for panadapter function. Why would he need to add another 8.83 MHz output on the TS-830S for connection to the SM-230 for panadapter function.

The 830 has 2 IF outputs. One goes to the IF input of the station monitor. The other goes to the vertical input on the monitor. The 530 requires a modification from the IF board to pick-up the 8.8MHz signal. I have the modification and circuit for anyone to use

50955. TS-520S Transformer HV

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-01-17 15:01:31 UTC
From: phoenixproject@...
Topic: 50955 Message: 50955

Hello everyone. I recently had a problem with my 520s,
HV went down to 400V (on the meter), and my output
went down to 40w. After following some advice, I tried to
test the transformer to see if it is bad, since sometold me
it shouldnt be it, but to test it anyway. I measured the 800v
line on the txformer, and it meaures 550V AC, which I think is ok.
When I turn on the heater, it stays that way, even when the tubes warm up.
But when I turn to Xmit, the voltage drops to 0V AC. I think it is an indication
of a short somewhere. Or is this normal?
One of the HV caps is brand new, and I've yet to test the other one,
which was also replaced a while ago.
Any ideas are welcome.

Thanks,

João G.

Pete,

If there is an 8Mhz IF out then no need to add an additional output.

50957. Yaesu FT707 repair ...

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-01-17 15:57:37 UTC
From: Behiels jean-Pierre
Topic: 50957 Message: 50957

Hi members;

I have some questions around a bandswitch of my FT707

I have some problems around wiring a mode switch,witch was bad mounted (srew not good tighten) the front panel of my FT707and has turned 360° due the use.

Some wires were broken and I did not yet where I have them to connect back on the switch due poor information I found on the service manual

I saw hier that my +8VDC supplied by the AF unit is dropping down in the LSB position,that means that +8VDC is somewhere due the switch connected to ground

(bad wiring I suppose)

But most important of all before rewiring the whole switch is to now what all those contacts on the switch himself means.

Do you have sometimes a datasheet from the switch himself ??

I do have a lot of wires but I could not direct follow what happens around the switch.

I could not find by a resistance measuring around the band switch,some connections who has to be made by example in the position LSB
!!!!!!!!!!!!!!

In this last example my +8VDC drops down !!

USB mode works like it must be what means that +8VDC common contact supply to the switch is correct made.

But where I connect the blue wire (LSB wire) coming from the AF unit on the switch ?

In position LSB I could not find on the switch any other contact witch is connected to the common of the switch (+8VDC red wire coming from AF unit)

I could be that the switch in broken inside,but it is a new one so that could not be the reason ..

I think there is a wiring failure,while in the LSB position I took down the +8VDC (+8VDC drops down I suppose due a faulty earth connection on the switch)

Also I saw on the page 3-64 of the user manual 2 designs of a switch but witch one is those I need ??

I presume I have to take attention to the design down under this page.

But I can not follow this design with what I see in the transceiver ??

A real datasheet of the switch himself will be mutch better to follow up.

I hope you can help with my request because.

I could nowhere found any datasheet of this Japanese switch . ????

S2 Yaesu FT707 part N0190014

S2 Chasis part number SRN2045N

I have also the impression that schematics and PCB layouts are not exactly the same has what I see in my FT707 serial 030254.

Behind that not to pseak about wiring ?

Maby there are made some modifications around the bandswitch als,who I not nows about ?

Kindly regards Jean ON4AEF.

My mistake, I missed/forgot about the IF out sockets, sorry about that.
Use the "IF OUT 1" since that's the RIF 8.895Mhz signal before the
crystal filters.

> One of the HV caps is brand new, and I've yet to test the other one,

Your problem is very likely right here. The transformer is presently OK, sounds like.

I prefer to replace the HV caps in pairs if at all possible. I guess that isn't really necessary, but it helps my peace of mind. I've got enough troubles.

Be CAREFUL while working on this, the high voltage circuit has enough power to cause serious injury or even death. Make certain the power is off, the plug is removed from the mains, and that the capacitors do not retain any charge.

The other parts sound fairly nominal to me - the filament voltage and the HV dropping to zero upon transmit. (By the way, don't do that again until the HV is repaired, if you want my advice - and not to perhaps need a new transformer. They're either expensive, or difficult to source, or both.)

A reduction in HV by 50% in transmit along with a reduction in power
output, clearly indicates a failure in one of the HV filter capacitors.
The HV power supply in the KW hybrids are all voltage doubling supplies
with both HV filter capacitors wired in series.

I agree, if a HV filter capacitor has failed, replace both caps.

Can a external VFO the the 520 be wired to a 530s
I had some Kenwood equipment given to me lastnight, TS-520, TS-520 VFO and an SP-520, and a matched pair of RCA 6146's. All have been sitting in a garage for about 10 years.
They all need some TLC, the paint on all is very faded but a good washing and some rattle can paint close to the Kenwood color is good for me..... the radio lights up but so far no receive, the inside of the radio is clean (no corrosion) just some spider webs that I've blown out, it still has the S200A1 tubes in it,
I would like to use the 520 VFO with my 530s when I get it back up and running.
I have the thread "530 no output power"
thank you
Dave KG6SVF

Topic: 50964 Message: 50965

Dave,

The issues about the compatibility of the VFO-520 and the TS-530 and TS-830 have been discussed many times.

The VFO-520 will not work with the TS-530. The VFO-520 has a lower tuning range, 5.500Mhz to 5.000Mhz (zero to 600 on the dial). The TS-530 has a VFO tuning range from 5.500Mhz to 6.000Mhz tuning range.

You said the TS-520 receive doesn't work. Did you connect the VFO-520 to the TS-520? If not you must insert the black jumper plug or short pins 8 and 9 together.

Did you receive the manual for the TS-520? If so you need to spend some time studying it so you can familiarize yourself with how to operate the TS-520. The TS-530 does not have the remote VFO socket jumper plug, it's build into the DIN socket

To all members,

The initial subject of this thread was

"TS-530s NO OUT PUT POWER"

Discussions about Dayton hamvention and whether there will be a forum
about a specific subject or not was not part of the initial thread!!

If you have an issue to discuss that is not pertaining to a thread's
initial subject of discussion, start your own thread!!

Hijacking a thread to discuss issues that do not pertain to nor are part
of an original thread's subject, is unacceptable and will not be
tolerated on this group!

Hi Dave and others,

I offer this advice with the best of intention and hope it helps others using this group. One of the things that is really easy to do is search for information using the group search engine. It's right there at the top of the page.

Emacs!

I just typed vfo 520 and then hit enter and got a whole lot of information about the vfo including the compatibility of vfos and models. It's quicker than writing an email.

I think what Mike was trying to say politely is that the VFO compatibility topic was discussed about a week ago. It happens quite often that a big discussion may go on for a week then only a few days after the discussion ends someone asks about that very topic. While we all want a quick answer every now and then the key to learning is study and research. The internet has made study so easy and most places you look do have a search facility. The user and service manuals are full of good information and coupled with the excellent advice already on this group should answer most questions.

Regards

Lou

Mike,

I made the assumption you were thinking about 530 series. Not sure if the SM230 has the pan adaptor fitted already and not an optional component. Only issue with the 530, 8.895Mhz mod is it tends to reduce the sensitivity of the receiver. I think it was Jan, who has done some extra work on a better modification for the 530 mod and has it working similar to the 830 series.

Subject: Re: [TS-520_820_530_830] SM 230 and ts 830 pairing?

My mistake, I missed/forgot about the IF out sockets, sorry about that. Use the "IF OUT 1" since that's the RIF 8.895Mhz signal before the crystal filters.

IF OUT 1 on the back of the TS-830S is an 8.83 MHz output (it's used with the SM-220/BS-8) for panadapter function. Why would he need to add another 8.83 MHz output on the TS-830S for connection to the SM-230 for panadapter function.

Pete, wa2cwa

You said:

"David,

The SM-230 has an input center frequency of 8.830Mhz which is stated in the SM-230 manual's specification page. This matches the TS-830 first IF frequency.

The TS-830's first IF frequency is 8.830Mhz which is the input frequency to the first 8Mhz crystal filter.

The SM-230 has an "IF IN" socket on the back panel (see paragraph 4.2 "REAR PANEL" in the SM-230 operator's manual.

The TS-830 will require a modification to add an IF OUT socket and connection to that socket from the 8.830Mhz first IF at the input to the 8.830Mhz crystal filter in order to connect the TS-830 to the SM-230.

It appears you do not have the electronic knowledge and skills to perform the IF OUT addition to your TS-830. Therefore, I recommend you find a local ham who has the knowledge and skills to perform this modification to your TS-830.

If you do not have the TS-830 operator and service manuals as well as the SM-230 operator manuals, then I recommend you obtain them before you attempt to make the connections between the SM-230 and your TS-830.

BLUF: I am taking offers for a recently working (but not now) and complete 520S. Has new tubes. If you are interested, email me an offer at KD0YMC@arrl.net and we can talk price and shipping.

The story, this is a rig I bought recently and was working within the last 3 months. It doesn't receive or transmit now. Not sure what happened.

I was going to put it on the bench and attempt to troubleshoot over time, but unfortunately, new assignment at work is not going to allow much free time in the future. Hopefully, someone with more time and skill will be able to get it working in short order. photos upon request, but this unit looks great (all bulbs, switches and nobs are there and function). Handle stitching has come undone. No significant marks or scratches. Has been re-capped. Non-smoking home.

I would love to keep this, but would like an operational rig, and time is not on my side for troubleshooting.

Regards,
Robert/KD0YMC

Actually Dave, I was thinking of the TS-520 series, they do not have an IF OUT connection to use with a Scan Analyzer whether it's the SM-220 with the BS-8 or the SM-230.

I had a similar issue with gain reduction when connecting my Heathkit HO-13 Ham Scan to my SB-303 receiver, HW-101 and SB-100 transceivers. Following the HO-13 manual recommendations on connecting to various makes and models of transceiver/receiver resulted in gain reduction, just as you described. I found the receiver's gain reduction was significantly reduced to a level that's not noticeable to the ear and S meter, was to connect at the crystal filter input switch. I used a single wire that ran along the wiring harness to an RCA socket on the rear panel. I used a 75 ohm video cable found in most DVD/DVR/VCR player/recorders. I kept the cable short, about 6 inches. The IF output to the HO-13 is more than enough to drive the PIP well above the top of the scope.

The TS-520S has the same 3.395Mhz IF as my HO-13 is configured for. I plan on connecting the HO-13 to the TS-520S by following the same connection point as I used with my HW-101 and SB-100 transceivers. Hopefully it will result in the same full gain operation as it did with the HW-101, SB-100, and SB-303 transceivers/receiver.

Thanks Mike,

Glad to hear someone else noticed the sensitivity gain. I gave up trying to use the Pan display with the 530, instead I use my spectrum analyser heavily antenuated, much more acurate and gives better reading without the reciever loss. Be interested in hearing how your HO-13 goes on the 520

Hi Dave:

Go to Clifton Labs website and look at his Z10000 Buffer Amp kit. This may resolve your loading problem. There may be other buffer amp kits available as well. I only cite him as he as a reputation of knowing what he is doing. I havent made an exhaustive search.

On the 530 you want to tap off before the ceramic "roofing" filter (CF-1/L2 junction). I would start with the same 47pf/10k combo that 830 uses and may have to try different values. I assume that is where you are at and the path you have been down.

This filter is first place in the path where pass band is being tightened up (approx 20khz) and provides some propagation delay so the noise blanker works properly. Dont tap on after CF-1 filter or further downstream at input to the IF Xtal filter as the passband has been narrowed.

If using a TS-520 series with a SM-220, the IF OUT connection mod (IF Sample Cable) is well-described on Page 16, Paragraph 8.6 (Figure 8-5) of the SM-220 Operating Manual. As for the Band Scope option for SM-220 for use with the TS-520 series, it's the BS-5, not the BS-8. The BS-8 was for the 820 Series only. I installed a BS-5 in my SM-220 for my TS-520S back in 1978. 73 Don W9CW

Don,

The discussion was about the TS-830 and the SM-230. I made the mistake of stating a connection would have to be added to the TS-830 in order to connect the SM-230 to the TS-830. My "thinking" was about the lack of IF OUT connection in a TS-520 which is how the TS-520 became part of the discussion. I am aware the SM-220's BS-5 is required to be used with the TS-520.

The AT200 antenna tuner operating manual says it is "... designed for use with the Kenwood TS520 and TS820 series."

Does that mean it is incompatible with the 530 or 830 series for some reason? Or were the TS530/830 series not yet made at the time the AT200 was produced?

Rob,

Do you believe the RF is different from a TS-530 and TS-830 than from a TS-520 and TS-820? You have misunderstood what the statement is telling you! The statement is simply telling you the AT-200's "cosmetic design", NOT the electrical/electronic design, is designed to fit in with the TS-520 and TS-820.

The RF is the same whether it originates from a Heathkit HW--101, Swan 350, Collins KWM2, a Drake TR3, TR4, T4X<any> transmitter, or any of the Kenwood series HF transceivers which includes the TS-520, TS-820, TS-530, TS-830, T599, TS-510, or TS-511 as long as the RF output level of the RF output from the transceiver is within the maximum RF limits of the AT-200 tuner. Therefore you can use the AT-200 with your TS-530 and TS-830.

Thanks, Mike. I figured HF was HF whatever tuner it passed through. Just wasn't sure if the x30 series transceivers had some functionality that would make it incompatible with the AT200. Appreciate you clearing up that it's cosmetics.

Also the AT-200 does not work on the WARC bands. The AT-230 covers all bands.

  The AT200 antenna tuner operating manual says it is "... designed for use with the Kenwood TS520 and TS820 series."

Does that mean it is incompatible with the 530 or 830 series for some reason? Or were the TS530/830 series not yet made at the time the AT200 was produced?

When I paired my Heathkit SB-620 Scanalyzer/Panadapter (set up for 3.395 MHz) to my Kenwood R-599D also with a 3.395 MHz IF, there wasn't enough signal coming off the first mixer to drive the SB-620 input. I built a simple 3 or 4 stage transistor voltage amp taken from the pages of the ARRL Handbook. Mounted the parts on a small perf board, and mounted it on the underside of the chassis. Mounted a RCA jack on the back of the R-599D. Output of the voltage amp goes to the RCA jack and a roughly 2 foot cable connects the jack to the back of the SB-620. It think I did this 20 to 30 years ago. Still works as I still have both pieces of equipment.
Pete, wa2cwa

You wrote: "I had a similar issue with gain reduction when connecting my Heathkit HO-13 Ham Scan to my SB-303 receiver, HW-101 and SB-100 transceivers. Following the HO-13 manual recommendations on connecting to various makes and models of transceiver/receiver resulted in gain reduction, just as you described. I found the receiver's gain reduction was significantly reduced to a level that's not noticeable to the ear and S meter, was to connect at the crystal filter input switch. I used a single wire that ran along the wiring harness to an RCA socket on the rear panel. I used a 75 ohm video cable found in most DVD/DVR/VCR player/recorders. I kept the cable short, about 6 inches. The IF output to the HO-13 is more than enough to drive the PIP well above the top of the scope.
The TS-520S has the same 3.395Mhz IF as my HO-13 is configured for. I plan on connecting the HO-13 to the TS-520S by following the same connection point as I used with my HW-101 and SB-100 transceivers. Hopefully it will result in the same full gain operation as it did with the HW-101, SB-100, and SB-303 transceivers/receiver.

Hello, I wanted to follow up on my on going TS-820S display issues. I think this will help others just starting off. Like most my DG-1 did not work when I bought the radio. I re-flowed the solider many times on both top and bottom of each board. Each time the display worked but only for a while. Each time I worked on the boards something else started working. The first time it worked I didn't know there was an extra digit. The next time I solider more of the top of the board the extra digit came on and therefore the RIT started working. It may have worked but without the extra digit I just though it was another thing to troubleshoot later. After reading all the posts about different radios and issues, someone last week stated that the user should check the VFO plug in back. Well for me that pass into one ear and out the other. Again my display went to 19.000.0 all by itself and it would not come back. Not wanting to take it apart during the contest on Saturday I wiggled the VFO plug in back and sure enough it came back to life.

DG-1 issues
re-solider the bottom traces - all chips and connectors
re-solider the top traces (where the rivets come out to the top and chip legs)
clean the molex pins with very small wire brush
clean the VFO jump pins (on back of radio)

So far so good....

Darrell

HI Terry,

Thank you, I did take off from the roofing filter, and have tried different combinations but still affects receiver, I'll have a look at the buffer kit and maybe install on the open 530s used for referencing. Appreciate your guidance.

Stay warm

Subject: RE: [TS-520_820_530_830] SM 230 and ts 830 pairing?

Hi Dave:

Go to Clifton Labs website and look at his Z10000 Buffer Amp kit. This may resolve your loading problem. There may be other buffer amp kits available as well. I only cite him as he as a reputation of knowing what he is doing. I havent made an exhaustive search.

On the 530 you want to tap off before the ceramic "roofing" filter (CF-1/L2 junction). I would start with the same 47pf/10k combo that 830 uses and may have to try different values. I assume that is where you are at and the path you have been down.

This filter is first place in the path where pass band is being tightened up (approx 20khz) and provides some propagation delay so the noise blanker works properly. Dont tap on after CF-1 filter or further downstream at input to the IF Xtal filter as the passband has been narrowed.

Interesting, Dave... I tried to open the prongs of the back plug a little, and one of them sheared off in the process, doggone it... so I just hooked up my external VFO that is having some trouble and just turned its switch to OFF.

I was able to transmit and receive in the North American QSO Party for a while with no problems whatsoever. Obviously that back plug was the culprit, but now that I've sheared off one of the prongs, I'll need to find another plug.

I've cleaned the external VFO thoroughly several months ago and seems like there's a relay in it that I cleaned the contacts as well, but it's not working correctly. At least it can make itself useful for a little while until I get a plug.

Anybody have an available plug for the back of a TS-820?

Or you can simply use a short piece of wire to jumper pins 8 and 9 on
the female side of the 9 pin VFO plug.

The jumper plug only has pins 8 and 9 shorted, no other connections are
in the jumper plug.

The voltage is only 9VDC that powers the internal VFO. Without the plug
or pins 8 and 9 shorted, the internal VFO doesn't work resulting in no
TX and RX.

Barry,
You can use a "socket saver." This looks just like the shorting plug...but has corresponding pin holes on the top, to which to put in a tube for various testing. You can usually spot them as they have a screw going through from the top with a nut on the pin side on the bottom. You would still have to connect pins 8 & 9. Many, including myself, just use a good piece of solid wire to connect pins 8 & 9. IMHO, about $10 is a bit steep for a shorting plug, when a 1 cent or less piece of wire can serve the same purpose. The 520 & 820 series came with the shorting plug as standard equipment. Hopes were that you would get the appropriate remote VFO..and have no use for the shorting plug. It would be interesting to see how many of the still functioning 520/820 series still have the OEM shorting plug.

I agree Joe, not many 520s and 820s have the factory jumper plug. I was lucky when I bought my TS-520S, it had the jumper plug. The 820 I had didn't have it so I used a short piece of solid copper wire connecting pins 8 and 9.

Barry,
The remote VFO for the 820 has the same VFO as the main 820(S), and will suffer from the same problem...which usually is a dirty/corroded wiper on the VFO's main shaft at the rear. The remote VFO is easier to work on. Also, inspect visually and electrically the remote VFO connection cord. Using your volt/ohm meter, check for pin to pin continuity while flexing cord

Barry,

What symptoms is the VFO-820 giving you? The relay inside the VFO-820 is used to switch between the internal VFO or remote VFO when the VFO-820 FUNCTION switch is set to REC or XMIT. The relay switches the VFO signal depending on what position the VFO-820 FUNCTION switch is set to.

For example, if the VFO-820 FUNCTION switch is set to "REC", the VFO-820 provides the VFO signal in "receive" and the TS-820 internal VFO provides the VFO signal for "transmit". The "switching" between the VFOs is performed by the VFO-820 internal relay. If this relay is not working properly then you will not see proper operation of the VFO-820. I had a problem with a VFO-820 I used with a TS-820S I had a number of years ago. I pulled the relay, took the cover off and cleaned each contact then clean the relay socket and finally the VFO-820 FUNCTION switch. Once I did that the VFO-820 worked perfectly. If you place the VFO-820 FUNCTION switch to "REC" or "XMIT", listen very close to the VFO-820 while pressing the PTT button you should hear the VFO-820 relay energize. If the relay does NOT energize then there will be problems.

Tom,
That depends on what you want. Items related to this groups function, Kenwood hybrids...problems/fixes/parts, and other items directly related to this groups function, and amateur radio in general.
It appears that you have not been a member long..and your posts are "moderated." If your "wanted" item(s) request is not in keeping with the above, it will be rejected. If someone contacts you stating that they have what you want, further communication(s) will take place off forum.

Wanted item(s) posts shall be signed with your name & call sign(if any)If you do not have an amateur radio call sign, your full name is required. Screen names are not permitted as a signature.

Looking for a mechanically and electrically great condition TS-830S.

Case is important, but is 2nd to full power output, no band switch issues, digital display "spot-on", factory sensitivity, completely recap'd and final cage modifications etc.

High serial number preferred.

Will pay fair market value for a great condition radio.

Thanks for reading this.

Mike, I can hook up the external VFO and use the Function switch in any spot, but I can't tell any change in the radio when I move the tuning knob. Seems like it's not getting a signal to the radio at all no matter where I have the Function switch.

I cleaned that inside relay and I think I cleaned the wiper in the external VFO, but I'll get around to doing that sometime soon to see if it needs any other work.

Thanks as always for your help!

Topic: 51001 Message: 51003

Mike,

There is a small panel on the side of the VFO enclosure. It's held to the enclosure by 2 screws. Remove one screw then loosen the other so the panel can be moved to gain access to the variable capacitor's flexible shaft to frame connection. Apply small amounts of DeoXit D5 contact cleaner to the flexible connection then rotate the VFO throughout its travel, end to end, a number of time. Next, use canned air, found at Walmart's television/CD/DVD/computer section, to remove the contact cleaner residue and dirt/dust. You may have to perform this cleaning process more than once depending on how dirty/corroded the connection is.

I have a video on my website that shows this variable capacitor flexible shaft to frame connection. The VFO in question is a Heathkit LMO (Linear Master Oscillator) but the idea is to show you, the viewer, what the flexible shaft to frame connection looks like. It's the same on the KW hybrid VFOs, just look for it through the side panel opening.

Be careful not to loose the small panel screw. If you do not feel comfortable performing this cleaning process then I recommend you find someone who has the experience. Also, use only enough contact cleaner to perform the cleaning job. Do NOT spray large amounts of cleaner into the VFO.

If the VFOs do not have a problem, erratic tuning, then you don't need to do the above cleaning.

You might consider trying to learn how to search for message text covering subjects such as this. You will have to log onto the Yahoo group's home page then use the search text block at the top of the page. Enter the text phrase you want to search for and click "Search Groups". Messages that contain text based on your search phrase will be shown below. You simply go through the various message text to find the information you need. The information is not always going to jump out at you, you have to spend some time viewing messages to find the information you are looking for. Searching for information is the same on the KW hybrid website as it is to search for information on the web. You won't learn how to do it if you don't try to learn how to do it yourself!!

One thing missed in the excellent cleaning post is that the little piece of metal riding the shaft to make the connection SHOULD NOT BE 'ADJUSTED' (AKA 'bent') to "improve the contact." You'll break it, or it will not ever go back where it ought to be.

That little bit of metal is a high-phosphor bronze with a very specific "temper" applied to it during manufacture. It looks really simple, but it's actually the result of a good bit of skull-sweat on the part of an engineer or two. Don't bugger it up, be really careful not to try to bend it at all.

And on the mangled mess which the yahooligans have made of a simple, once-useful web site, the "search conversations" box near the top will perhaps give you the postings about this if you search for the two words

bronze wiper

Or not, right now I can't tell WHAT the results are, really, because the most recent round of "site improvements" has placed a large blank rectangle smack in the middle of the Kenwood hybrid page. I can see a few words on the left of it, and it appears to be the post from Terry about the air-variable caps, but the most of it is blocked off.

(Seems to be some kind of crappy ad, which just refuses to die, I am guessing. I wish this list would move to somewhere without all the crud. I know, I know. "Off topic," and no matter how many nor how much I or anyone complains or hates it, nothing will change. But the yahooligans make my sysadmin sensibilities just -ache-. I've run web farms for a living, and THAT just ain't how it is done.)

Yes, the flexible connection is very fragile. At no time should the flexible metal be lifted or pressed since this can easily bend the thin metal making the problem "worse"!!!

If the grease in the VFO bearings is old, dirty, then I would recommend removing the VFO from the radio then take the metal enclosure off the VFO. This will provide better access to both points for cleaning. Care must be used to ensure you do NOT damage the VFO components, circuit, and variable capacitor plates.

Cleaning the old dirty bearing grease will require one to replace the grease. I use DeoXit L260Ap conductive grease. You can find it on eBay in a 28gm plastic container. A 28gm plastic container will last you forever!! Simply apply a small amount of conductive grease to the bearings using a flat tooth pick or a small thin flat plastic applicator, then rotate the capacitor shaft while holding the tooth pick or applicator flat against the ball bearings. This helps coat the ball bearings and fill up the void between the bearings and the capacitor's frame with the conductive grease. Remove any excessive grease and DO NOT allow excess grease to fall onto the VFO circuit, circuit boards, or portions of the VFO circuit as it's conductive and can cause a short!!!

I have a Heathkit SB-303 solid state receiver that would give me fits when the LMO flexible shaft would get dirty. Cleaning the flexible shaft connection wasn't enough since the problem would return after a week or so. I decided to remove the LMO and thoroughly clean the flexible shaft to frame connections and remove all the old conductive grease and apply a new layer of Deoxit L260Ap conductive grease. The LMO has not given me any problem since then!!!

TS520SE

Very low RX.

The problem turned out to be Q3 on the RF PWB. Not an original
replacement (SK3187) someone had inserted it 90 degrees out of position!!!!!

Never trust a prior (attempt at) repair.

Replaced the SK with an original type 3SK35 socketed correctly.
Sensitivity went from 1 mv to1 uv!

Thanks to Mike and those who offered advice on this one.

Mike, I'm playing around with my VFO-820 now. If I have the radio Function switch on VFO.R I can get the external VFO to work receiving - but only if I have the external VFO switch IN BETWEEN the options. If I want to receive, I can put the switch BETWEEN OFF and REC - like it isn't making a good contact on REC where it is supposed to be.

It will not transmit near REC/XMIT, though - the display just goes blank and there's no output looking at the meter or at my Micronta SWR/Power Tester.

Barry,

Now, based on your symptoms you have described, it appears the problem is with the VFO-820 FUNCTION switch. I recommend you remove the VFO-820 from the TS-820, install the shorting plug or a piece of wire between pins 8 and 9 on the remote VFO socket so you can at least use the TS-820 then spend time troubleshooting the VFO-820's FUNCTION switch. The VFO-820's schematic can be found on page 71 in the TS-820 service manual. The VFO-820 connecting cable is wired pin to pin. This means there are NO jumpers or shorting connections between pins. Pin 1 on one end connects directly to pin 1 on the other end and so on for each pin.

I recommend you spend some time studying the TS-820's PLL system so you understand why the digital display went dark and the TS-820 no longer has TX and RX functions. The TS-820 PLL system is discussed at length in the TS-820 service manual. The TS-530 and TS-830 also have PLL system. The TS-520 does not.

Search for DG-1 within the group. You will find some treads on this display.

DG-1 issues
re-solider the bottom traces - all chips and connectors
re-solider the top traces (where the rivets come out to the top and chip legs)
clean the molex pins with very small wire brush
clean the VFO jumper pins 8&9 (on back of radio)

Hi, I am new to the group and did a few searches. I have a working TS-520 and just purchased a spare TS-520 for spare parts for only $40. Now I want to get it working and it also needs three sheet metal panels, which I COULD make, but if I can find some used for not to much, that would be preferred. I am missing the top cover with speaker, the RF Final cover sheet metal and the small side controls sheet metal cover with plastic hardware. Please let me know if you want to sell these for reasonable. I am in Sacramento, CA.

Thanks,

Larry AJ6G

51016. DIY Frequency Display for TS520?

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-01-23 12:36:06 UTC
From: yahoo@...
Topic: 51016 Message: 51016

Although I'm just getting back into ham radio (active '70-'90's), I recall a project I had done to a TS520S.

Having only an analog display on the Kenwood, I noticed that there was a breadboard style Frequency Counter in the ARRL Handbook for 1978.

So, several parts later, and connections to the radio's BFO, HFO etc, I was reading 1/sec freq updates on the counter for all bands :)

It was about the size of a DG5 style counter, yet not quite a fancy looking.

I think of the small black box with 5 red LED's often, and wonder where the radio and the counter is now.

I've seen some 3rd party freq counters lately, but for me, I really enjoyed putting something together that really worked.

If anyone comes across a non Kenwood "DG5" type counter for the TS52* series, please let me know.

Thanks!

This is what my 820s display looks like if I leave the shorting wire (or plug) out of the external VFO socket in the back. Is the radio otherwise working? If it is, this is likely not your problem.

If it lights up but otherwise doesn't work, that may be it. Pins 8 and 9 must be shorted for the radio and display to work

Hi Mike,

I am new to the forum and don't have Bob Mansker's email address. Do you have it or know where I can find it?
Also, I am just getting back into ham radio after many years, so a LOT has changed. Maybe there is a web site that lists emails for hams around?

NEVERMIND! I googled him and now have it. I will send him an email right now.

Many thanks.

51028. Replacement Adjustment Covers

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-01-24 17:30:00 UTC
From: roberteleazer@...
Topic: 51028 Message: 51028

The side adjustment covers on both my currently operational TS-520 and TS-820S are missing. I have been planning on fabricating new ones out of aluminum sheet and decided that when I did that I would simply install nutplates on the top cover and use machine screws to hold the side adjustment covers. I have plenty of aviation style nutplates for that purpose as well as a rivet squeezer.

But I noticed something on the TS-520 I have been working on and saw a better approach. Simply buy some clip nuts at the hardware store (e.g., Monadnack Clip Nuts) and slide those over the holes on the top cover. Then you can fabricate new covers and attach them with either sheet metal screws or machine screws, depending on the type of clip nut you use.

And while I have AL sheet available I think I may try making a cover out of clear Lexan and see how that works.

Good Luck!

Robert

Topic: 50964 Message: 51031

Yes, Dave, the RCA 6146Bs are fine to be used in the TS-520 series.

If you didn't have to pay for the matched 6146s that's good because there is no need to waste money on matched 6146 tubes. You might be told by some people/hams that you should use matched 6146s. Don't believe it. There are plenty of hams who have wasted money buying matched 6146s. You will NOT notice any difference nor can you see any meter differences when buying and using matched 6146s.

51032. Using a SDR RTL2832 as a pan adapter for my TS-820s

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-01-25 01:43:53 UTC
From: gigahacker@...
Topic: 51032 Message: 51032

Hello, there are many threads about this (on the net) but it seems everyplace I read the thread loses focus and never answers the question. I have, and use many of the RTL USB adapters in the VHF range. I was thinking I want to use one of these as a pan adapter on my TS-820s, The IF frequency of the radio is 8.83Mhz and the DSP receivers only cover 53Mhz to 2Ghz. That said, I understand that with each receiver stage the IF the frequency goes up until it reaches the RF amp. I need to tap into the radio somewhere above 53Mhz. Any thoughts or help on this would be appreciated. A picture with arrows would even be better :)

Example from the net (but this is for a TS-850 not TS-820):
"You will see a lot more than 100 KHz with the USB dongle. The 8.83 IF tap is designed for the SM220 and SM230 scopes. Unless you are using a Softrock kit or, if I recall, LP Pan may work, that signal WILL NOT work with the USB dongles. They will not tune low enough.

TP-1 on the RF board will have the 1st IF signal of 73.05 MHz on it. This is easily within the tuning range of the dongle. You should be able to remove the top cover and test. Depending on your sound cards sampling rate, you should see at least 1MHz on the pan-adaptor. You do not need any other parts, other than a USB extension cable, an RCA jack to get the signal to the rear panel, some RG174 coax and a suitable cap for tapping. I used a 0.047 uF tantalum.

The extension cable is used to keep the dongle away from the PC to reduce noise pickup. The same RG174 cable can be used to connect the IF signal from the radio to the antenna input on the dongle. I used the antenna cable that came with the dongle."

From: Bob
Topic: 51032 Message: 51033

Darrell: There are devices for sale on eBay and other sites that are used with the RTL USB to extend their coverage downward to below the broadcast band. This is what I intend to do with my TS-830 shortly to use the SDR as a pan adapter as well. Prices seem to range from about $30 to 50. This way you can use the IF output, although you may need an attenuator. Some of this information I got from Jan, several months ago.
Thanks & 73

I must be very confused? The TS820 has no 73mhz IF at TP-1 or any place else?

In order to use the Dongle with any of the KW hybrids you will need an Up Converter and not a down converter.

Here is one that has good reputation

From: Jan Servaites
Topic: 51032 Message: 51037

That's a lot of bad information there.
First, (as Terry has mentioned) there is no 73.05 Mhz IF signals in any of the early Kenwood hybrids (and other brands from that time period).
Second, these "cheap" dongles may have on an 8-bit ADC (analog-to-digital converter) and that's LESS resolution than a standard PC sound card's ADC (16-bit @ 44khz).
Thirdly, if you insist to use these VHF/UHF TV dongles at HF frequencies, you will need an up-converter (as Terry mentioned), that may cost up to $50. So now you may have about $100 in a HF dongle setup.
Well, for about the same price, you could purchase the Soft Rock Ensemble II, purchased assembled for about $100 (kits are about $75).
Then using your PC's sound card, you will have a very nice panadapter using the HDSDR "free" software. This is a much easier & more successful way to go, in my opinion. Also, I use the one Softrock SDR panadapter for ALL my radios including my Yaesu 901s, Tempo 2020s, Hygain 3750, Kenwood twins, all my TS-8xx, and the TS-900 and the TS-430 & TS-940.
I have lectured on this subject at the last Hamvention forum, and you might look at my slides to get an idea for you guys that need some guidance on this.
Also to mention, Kenwood has documented a lot of good info in the SM-220 manual for radios that don't have the IF jack on the back panel. You can pick off enough signal (it might be too much, and I throw in some attenuation using a "Kay Electric" step attenuator) using a 47pf mica capacitor for my Softrock. I wouldn't use anything larger in capacitance, like a 0.047 uf tantalum as mentioned below.

Bob,

I think those are made by "Philmore" under the part number PH-61-604.
That part number is for the 4 pin female plug assembly.

You can buy them at the following online website

http://www.intertexelectronics.com/Philmore-61-604-4-Pin-In-Line-Female-Mobile-Connector-P10328.aspx

for $2.17 each. There may be other websites, including eBay, that sell them.

Bob,

I forgot to include the chassis socket that's found on the front panel
of KW hybrids is made by the same company, Philmore, under the part
number PH61-624 which is available at the same online store's link for
$2.02 each.

Ken's Electronics also sells the plug and sockets:

http://www.kenselectronics.com/lists/micplug.htm

for a dollar more.

Thanks Mike,

I'll check. I need some two pin or three pin versions for an instrument project.

I'm making probes for Boonton Millivoltmeters. And the Amphenol connectors are too expensive.

I'll just use the Amphenol connectors on the meter end of the cable.

Hi Brian,

Many thanks. That was my plan if I don't come up with one soon. Not too difficult to do and having the clips available helps. I now need to determine if spray cans of matching (or close) paint are available. If you know of a source for the matching paint, I would be interested. I might also make the top cover from some thick aluminum I have. That should not be too difficult to do either. I will likely make the speaker opening round so it will not look quite original. I should be able to find a better speaker around.

73,

Larry AJ6G

Hi Bob ,Mike et all,

I hope this finds you well. The connectors in question for many japanese radios (and the flex radios too) are known as Foster connectors and come in pin configs from 2 to 8. They also have been known to masquerade as CBC connectors. They are available from a wide variety of sources Philmore being one. Another Western distributor is Calrad. The ones on your Boonton are probably Amphenol 75MCXX series which you're probably familiar with from early Heathkit gear (both ham & test) they're a bit harder to find than hen's teeth and that probably explains the high cost. The other series of amphenol connectors used for ham & test gear was the 91MCXX series (the connector on the D-104 mic head & G-stand). Unfortunately none of the Amphenols are compatible with the Foster Connector for direct plug-in. A source I've used here in the Mid-West /East is Tower Electronics who sell these in cable-end male & female and chassis mount from 2 pin through 8 pins
as well as right angle cable ends. They have them in their brochure as CBC connectors. They make the rounds of the Michigan & Ohio swap-meets and thier quality is pretty good for a reasonable price. I imagine you can get these on e-Bay pretty cheap as well. I also buy from DC Ace at the local swaps. Both Tower and
DC Ace can be found on-line if you're interested in shopping. They both offer a wide array of connectors and other "junk box/drawer" parts at a reasonable price. R & L also sells the Philmore stuff.

I hope this excess of info helps.

Best Regards,

Mike K8SYN

in frosty ol' Michigan

51048. Hybrid Net Update (January 25, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-01-25 20:00:30 UTC
From: Mark Gilger
Topic: 51048 Message: 51048

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by Jimmy, WB2KNR.
There were 26 stations checking in under good band conditions.
We had the following number of radios checking in.

5 running TS-520(x)
2 running TS-530(x)
4 running TS-820(x)
5 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

Jimmy was running my TS-520 a Heathkit SB-200 amplifier.

The Sunday net was run by me, WB0IQK. There were
20 stations checking in under fair band
conditions. He had the following number of radios checking in.

5 running TS-520(x)
1 running TS-530(x)
1 running TS-820(x)
2 running TS-830S
1 running TS-510
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-940S + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total 142, Sunday☐s total = 88
December 2014, Saturday☐s net total 92, Sunday☐s total = 86
January 2015, Saturday☐s net total 110, Sunday☐s total = 84 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Hi Again,

The 2 conductor mic. connector for the Heath & others was the 80MCXX series. (Replace the XX with 2M or 2F to get the right gender. These were all very common on the old boat anchors in the 50's, 60's, & 70's. Pretty much before the Japanese invasion of Ham & CB gear. Those were good old days for sure. Most all these parts, foriegn & domestic, were off the shelf back then.

I know all about the microphone connectors used on the Heathkit stuff. They were made by Amphenol. All but the single pin are out of production.

There are (or were) still some of the 2 pin connectors in distributor stock but they were more expensive than the ones being sold on eBay.

I want a lower cost alternative and from a source where there is current production.

Hi Tom,
Its posted here:
http://wb4hfn.com/KENWOOD/Kenwood-Articles.htm

This is where we post all the groups articles for Kenwoods.
Like I mentioned about the SM-220 Station monitor, I would download the SM-220 manual, and study the part where they discuss where to pick off the IF signal. Its usually right before the SSB filter, where there's a LOT of signal gain available.

Bob:

Check out the CA092, CA093, CA102, CA103, CA104, CA105, CA108, CA109 connectors at FairRadio.com. They are very inexpensive, of excellent quality, and robust enough to carry some power if required. I installed one on a control board I built a friend.

I dont agree with tapping the IF just ahead of the IF filter for a panadapter. Why would you want to tap off where the bandwidth has been narrowed by a "roofing" filter. No reason to limit the bandwidth that the panadapter can see.

Look at the TS830 and you will see they are tapping off before the CF-1 ceramic "roofing" filter. That filter tightens up the passband to approx 25khz to deal with strong signal intermod and provides some propagation delay so that the noise blanker will function properly. Same function that the half-lattice crystal filter does in the TS820.

I cant imagine the SM-220 instructions telling you to tap at the input of the IF filter on the TS-820? I am quite certain you would want to tap right at the Molex Conn Pin 1 where the full bandwidth RIF signal enters the IF board and is coupled via C1 220pf.

Just past C1 you have T1 and the 8.834 mhz and 8.814 mhz crystals in half lattice config. The 3dB roll off of that "roofing" filter is approx 1.5x the difference between the two xtal frequencies for about 30khz bandwidth (a little wider than the TS830). Would never want to tap downstream of this filter.

On the 520 the first place they start tightening up passband is the T1,T2,T3 BPF at input to the Noise Blanker board so I would tap off at the output of Q9 VFO Mixer or at input to the Noise blanker board. Could probably just get on NB-1 wire wrap terminal post on the IF board.

If you dont have enough signal level can always build a simple one FET buffer amp.

All, thank you all for your comments. After reviewing all the comments and some more on-line reviews I am going with Jan's suggestion of using Softrock. After finding Jan's QRZ page and seeing what he is doing and writing Software Rock and getting their reply.

I have found there is nothing higher then 8.83Mhz available, the RTL is not good down in that range. Using a Up converter is addition money.

Here is something you may or may not know. Review this link:

There is a version of SoftRock just for IF for PAN use without the other options for 1/4 the price of what I was expecting to pay. This is without a doubt a better route to follow.

Darrell,
You may or may not like it. That is the crystal controlled local oscillator version of the Softrock. The LO cannot be moved.
The EnsembleII's LO is variable, and can easily be moved within the HDSDR PC program. Why is it better (in my opinion)? Well, I describe this is my lecture. The thing is the 8.83 "listening window" is moved a little too much to one side of the 48khz spectrum and that limits some on your viewing area and it's locked there. They say that the Lite version works better with the 96khz sound cards (and that could slow down your computer especially with an old PC), so that might mean the purchase of a new sound card and going through the Plug & Play & Pray thing with your PC. So, here again you are up to about $100 anyway (with a new sound card purchase, perhaps) and you ARE STUCK at 8.83 mhz!
The Ensemble II is a full HF receiver, so it can be a second receiver in your shack. Just something else to consider the added capability here..

Terry,
I apologize, I was just talking in general on where to look at and tap the IF. Kenwood & Yaesu (in their TS830/ 940 and FT901/902) provides the IF tap for their station monitors, so its a no brainer. If one follows the SM-220 manual, it gives a good overview on where to tap it in the older rigs like the 820 and so on, so that's pretty much a no brainer as well.
Now for radios that are missing the IF jack, and was never installed like my Tempo and Hygain rigs, then yes, your discussion on where the best place to pick off the IF should be followed and then tested with a probe to see how it affects the RX circuit. I made up my own "probe" using a piece of RG-174 with a 47pf cap soldered to the center conductor, and then I can probe around with it and choose the best place in the IF chain to pick off some IF.

I powered up the TS-520 I have been working on and it receives pretty well, even before alignment. Even more importantly, it did not produce either fire or smoke.

However the meter is flakey. The S meter function does not work very well, even though I set it to zero per the manual and then tried to adjust the sensitivity it's only a little better. It will require some more work. I guess I will try setting the level it at 14.175 MHZ per the manual before doing some troubleshooting - but it seems to me that both the VR1 and VR2 trimpots are acting rather erratic. I tried cleaning the pots with some electronics cleaner and I suppose a little LPS-1 will be applied next.

Also, while I have measured the newly repaired HV power supply at 944 VDC, on the HV setting the meter does not move. I guess that I'm not surprised that measurement seems to have been disconnected, given the number of wires that were cut in the power supply section, but does anyone have any suggestions as to where I should look?

Thanks!

Robert

Robert,

The HV meter setting works in transmit only.

A heavy gauge RED wire connects the Rectifier Unit's "800" terminal directly to the HV Unit's "800" terminal. This connects the filtered DC voltage to the HV Unit.

A heavy gauge BLUE wire connects from the HV Unit's "800" terminal to the positive terminal of the HV filter capacitor C16. This wire connects the 2 series connected 120ufd 500VDC high voltage filter capacitors to the high voltage power supply output.

A semi clear wire connects from the HV Unit's "800" terminal to the top side of the final amplifier to RF Choke L1 inside the final amplifier enclosure. This wire provides plate voltage to the 6146Bs/S2001A final tubes. This wire could be dark grey or appear like the inside conductor of RG8x coax. This wire is routed from the HV Unit up along the back panel to a hole in the chassis to the RF Choke L1, the RF Choke that looks like a resistor inside the final amplifier enclosure.

A White/Yellow wire connects from the HV Unit's "HV" terminal to the METER switch "HV" terminal. This wire connects the HV Unit's meter resistive voltage divider to the meter switch "HV" terminal.

The wire colors are what I see in my TS-520S. Hopefully your wire colors are similar.

Jan

No apology is in order. What I read or thought I read regards how you tapped the IF on your TS820 just didnt make sense to me.

I did go to N6WK website and found the SM-220 manual that had the BS-8 in it and the tapping instructions could have been more clear.

On the 820 they do show tapping at the RIF input to the IF board ahead of the half lattice filter, but the drawing isnt very clear and the grammar is poor as they say to connect the "capacitor end of the coax to the "RIF GND terminal.....". What the heck is the"RIF GND" terminal? This could be very confusing to some folks. At minimum should say connect to the "RIF and GND" pc pads or foils.

Better would have been to state something like " Connect the center conductor of the coax with a 47pf series capacitor to the RIF input solder pad and the coax shield braid to the closest ground foil on the bottom side of the IF board near Molex Connector Pin 1". Maybe back in that day when we were still pounding on typewriters it wasnt easy to include a copy of the x-ray board view with arrows pointing to the tap points.

Hi,
I just want to give a huge thanks for this great site helping resurrect Kenwood hybrids. I have a TS-520 that works fine and a "spare parts" TS-520 that I have decided to look at and see if I can get it running as well. After finding this site I can see that I will eventually want to improve the tube protection portion of both rigs. I received help in getting the missing sheet metal panels for the parts rig. As received the parts rig is extremely dirty inside and neither the receiver nor the transmitter were working. Not having a top cover as received really made a mess of the insides.

Last night I was checking the receiver and it appears that it was not receiving signals from the antenna. The WWV part did receive, so I was encouraged. I found there was an open path from the input to the ANT connector. The schematic showed the other input is also connected to that path and there was a connection from there to the ANT terminal. This AM I connected the antenna to that other input and, sure enough, I was able to receive signals for the first time! Now I "only" need to see if the broken path is the input relay or something else, but at least the radio appears to receive fairly well.

As for the transmitter, I noticed that the finals have no screen voltage, but there is screen voltage at the rectifier board, so that should not be too difficult to find, hopefully. I checked the 12BY7A on a tube tester and it seems fine. I have a stash of spare 6146s so that should not be a problem.

I will take the advice about repairing many of the "normal" and frequently needed replacement parts, i.e. electrolytics and some of the weaker parts pointed out by the experts here. I want to have both rigs working well and reliable as backup rigs for each other.

I know the AF and RF controls need cleaning as well as the rest of the insides to eliminate all the grime and dust bunnies in there.

I have to replace two pilot bulbs when I get a chance, but will wait until I find that I need to do front panel work in addition to getting in there. I found the sites where I can get spare parts for reasonable cost.

I have found one spurious signal on 40 or 80 about 220 on the dial and will attack that after getting the receiver and transmitter working reasonably well.

Thanks again and 73,

Larry AJ6G

Mike/Robert:

If I might add Robert may want to check the HV divider string resistors. Pretty common for one or more of the carbon resistors to go very high or open. I would measure HV terminal to chassis ground in RX mode and with rig flipped to Send in SSB mode and meter in HV position.

In RX mode will read something on the order of approx 44.0vdc. This is due to the 2meg/100k ohm divider or approx 20/1 ratio or 900vdc/20 = 45 vdc. When I first saw this I about had heart attack as I knew the meter movement could never survive application of 45vdc across it.

When you flip to send in SSB mode will see something around 0.245vdc which will give you the 900vdc indication on the meter which has a full scale deflection of approx 0.275vdc. How does this happen?

When you flip to Send the Aux relay places the panel meter movement across the 100k resistor in the divider string and the internal R of the meter movement (550 to 600 ohms) changes the divider ratio. With 550 ohms placed in parallel with 100k the 100k is now invisible and the divider ratio has been changed from 20/1 to approx 2meg/550 = 3635/1 or approx 900/3635 = 0.25vdc. Pretty cool!

It took me awhile to figure this out and need to know the internal R of the meter movement. This is what prompted me to start measuring all the Hybrid meter movement FSD current and internal R. I have all of them recorded. For new folks DO NOT take your Simpson 260 on ohms scale and attempt to read your meter internal R.

I always replace these HV divider string resistors with metal film.

I just tested my TS-520S IF Unit "NBO" terminal connected to my Heathkit HO-13 that's set up for 3.395Mhz IF. I used a shielded cable with a series .01ufd cap connected to the IF Unit's "NBO" terminal. The HO-13's display is very good. Receiver gain reduction is nill. Just have to install a spare RCA socket on the rear panel, label it "IF OUT" and connect the series capacitor and shielded cable to the Noise Blanker OUT terminal.

I've used my operating position as a bench too so I know how that gets
crowded.

If you look at the schematic you will see that RL2-2 relay terminals
controls the meter. The TS-520 schematic shows the relay in receive so
the meter is connected through RL2-2 to the IF Unit's "SM" terminal.

Energizing RL2-2 you will noticed that the meter connects through MR2
and MR1 on the Final Unit back to the meter. You will also notice that
the relay connects to the meter switches "ALC" terminal. This is because
when the relay is energized and the meter switch is set to ALC, the ALC
produced is fed back to the IF Unit and is displayed over the "SM" path,
same as the receiver's S meter is in receive. The IF Unit's "SM"
terminal is "common" to both transmit and receive in displaying AGC
variation in receive based on receive signal strength and transmit ALC
variations in transmit (TUNE drive adjust and normal sideband voice peaks).

Jan:
It is true that all Service Manuals are written to an assumed base knowledge and experience level of an experienced technician and not necessarily a owner/operator.

That includes not only knowledge of the radio design, physical layout, test point and adjustment device locations, but also the knowledge of how to use the prescribed test equipment.

For that reason not always a lot of meat on the bones. Of course the translation factor also can complicate things.

This is also true for technical procedures for operators and maintenance personnel. In Nuke power we even had an assumed reading comprehension level and surprisingly I wont tell you what grade level of education that was. Lower than what you might think.

Terry,

No I only tested to see if NBO would work. I must admit I spoke a bit too soon. I tuned in a fairly stable 20 over 9 sideband signal and connected the HO-13 to the NBO terminal. I did notice a small amount of receiver gain reduction, didn't see it before, possibly due to the constant changing sideband signals. Therefore, further testing is needed, including the IF Unit's NBI terminal.

I had to adjust the HO-13's PIP gain to 12 o'clock, it was set for the HW-101, SB-100, and SB-303 Heathkit transceivers and receiver. I may also try a couple different series capacitor values to see what differences they make.

Mike:

Yes I was going to mention that .01uf is very large coupling cap to tap IF, but I dont know what signal level it takes to drive the HO-13. I would try 100pf or less.

If I get time will sweep the BPF at input to the 520 NB to see how wide it is. My guess is that it will be approx 25 khz similar to the ceramic and crystal filters in the later Hybrids at this same point in the IF path.

I just swept the TS820 Half Lattice Xtal filter and the TS-830 CF-1 ceramic filter on couple of spare boards and will see if I can figure out how to add them to the files.

Yesterday I said rule of thumb would be that bandwidth of a Half Lattice Crystal filter is approx 1.5x the frequency delta of the two crystals which would then be approx 30khz. Well actual bandwidth at 3dB rolloff is approx 24.5khz. So good reason not to tap the IF downstream of this filter in either rig for panadapter feed.

My TS-830S is just about dead on receive ... but only on 20M. All other bands receive as they should. It's currently on 15 meters. On 20 meters, I'm lucky to barely hear one or two signals (the band is not dead). When swapped out, other radios receive 20M just fine ... the band is loaded with signals. Put the 830 back on line and condition is as described above ... like a 60 db attenuator is in line. It transmits on 20 meters as normal.
Suggestions? What should I be looking at ... and where is it located?
Thanks, in advance, for your help.

Well, in the 21.5 years I have lived here, I have been to the Orlando Hamcation 2 or 3 times. Usually I think I'd like to go, and then look around at my accumulation of uncompleted projects and realize even if I bought something I would have no place to put it and no time to work on it. Why, I even did troubleshooting on an Icom IC-560 I bought at the 2013 Melbourne Hamfest and know just how to fix it if I get the part I need, and I have a part that might even work - but have done nothing else with it.

Thanks!

51078. TS520 - Sticky relay?

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-01-27 15:11:46 UTC
From: haYnguy@...
Topic: 51078 Message: 51078

I've noticed that after I key up and release the key, it sometimes takes a couple seconds before I receive again.

Steps taken:
1.) Key up, transmit - I hear the relay switch on, and can transmit just fine. No delay.
2.) Finish transmitting, and release the key - I hear the relay switch off but don't hear anything for a couple seconds.

Note: the time between me hearing the relay switch off and hearing sound from the rig can be anywhere between less than a second up to 5-6 seconds. Also, I don't have this issue when using CW.

My guess is that the relay is sticky and doesn't fully close all the way sometimes. But, I figured I'd ask here first to see what you all say.

Thanks and 73s,
KF5YPD

Lance,

The Control relay you are referring to is RL1 located below the MARKER Unit and VOX Unit boards, top back left corner of the chassis.

You say the problem only affects sideband not CW. How are you keying the transmitter in CW? Are you flipping the SEND switch UP to key the transmitter then pressing the CW key etc to send CW? If so then you might try adjusting the VOX DELAY pot located on the left side of the transceiver behind the small removable plate. The same RL1 control relay is used in ALL modes and the relay, in receive, is not energized.l

Hey Mike, thanks for your response.

When I use CW, I keep the SEND switch down, and set the VOX switch up. That way, I don't have to switch the SEND.

I'll give adjusting the VOX DELAY pot a shot later on today.

Hi Chris:

Couple of things

1. Try cleaning the bandswitch contacts. These are on the red/brown vertical boards on the RF board. There are 7 of these boards and the two you are most likely concerned with are numbers 2 and 3 from the front panel with No. 2 switching in the 20 meter tuned circuit for input of RF amp Q1.

You can spray Deoxit "at" them or you can apply it with an artist brush and exercise the switch back and forth and then blow off with canned air. Not easy to get the cleaner directly on the offending contact. If it is due to loose high resistance contact then no amount of contact cleaner will fix it.

2. Can try adjusting the Ant and Mixer coils for 20 meters, but not likely the problem if it was working on 20 and then quit. If no RF sig gen can do this with the Marker signal. Instructions are in the Maintenance section of your owners manual.

The fact that you have good RF drive (good ALC indication when peaking during loading procedure) on 20 meters tells you that the Mixer contact on the 4th vertical board which is shared in Rx and Tx mode is not the issue. That leaves the Ant coil contact on the 2nd board. These vertical boards have issues with loose rivets that apply the pressure to make good low resistance contact between the hair pin turn and the mating solder pins to the RF board.

Go to W0NTA website to see what the boards look like and his repair procedure. He also repairs and tests TS530/TS830 RF boards sent to him.

I checked NBI terminal and I can get a strong display on the HO-13 but the series cap has to be a value higher than 100pfd.

I tried 100pfd and the signal display is too weak. Next I used a 220pfd, only a slight improvement. Next I tried a 400pfd resulting in a much better signal but still not strong enough to push the PIP to the top of the scope with the HO-13 AGC turned OFF and PIP gain set at 12 o'clock. I switched to 500pfd, the display hit the top of the scope without any changes in the HO-13 controls. If I go higher, the signal to the HO-13 improves significantly but receiver gain does appear to drop somewhat (1/2 S Unit). I used both off the air signals and the Marker signal(s) for testing. All caps have a 10% tolerance so the values could be different than the actual figures stated.

I'm going to settle with the 500pfd as the series cap. Since I'm not going to use or mount the DC to DC converter, I plan on removing the rear panel cover plate and use it as a template to make a cover plate from scrap sheet aluminum I have in the shack so I don't have to drill a hole in the original cover plate. Once I have the socket mounted and the connections made, I'll make a video showing the HO-13 and TS-520S then upload the video to my website for those who are considering doing the samething with a Heathkit HO-13 and/or an SB-610 set to accept 3.395Mhz IF signal or a Kenwood SM-220 with BS-5 Pan Adapter installed.

Another thing I like about the SoftRock SDR Pan is it's sensitivity.
Using the IF pick off, 47pf mica cap, I have to throw in about 10db-20db
of attenuation, so that the SoftRock is not over loaded with IF signal.
I have observed that the Kenwood radios have gobs of IF signal power. My
Tempo, Yaesu and so on, put out about the right amount, and I don't need
any attenuation (and doesn't load down the IF signal adversely too)

I suspect you built your Ensemble? Does it have SMD components?

If so might need to advise new folks about any difficulty with this and perhaps they should consider buying it already built?

Or perhaps they should by one of the "How to solder SMD" kits before taking on this build?

51088. TS-520S to Heathkit HO-13 Ham Scan

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-01-27 21:15:08 UTC
From: Mike W5RKL
Topic: 51032 Message: 51088

The IF tap at the TS-520S NBI is complete.

I used the DC to DC converter cover plate as a template to make a second cover plate to drill a hole for an RCA socket. I kept the original plate that will go with the 520S if I ever sell it.

Once the plate is made and the holes have been drilled, I mounted an RCA socket to the plate. I connected a 500pf disc capacitor to the center terminal of the RCA socket and shield to ground. I connected the other lead of the capacitor to the coax cable's center connector.

I ran the coax along the right edge of the MARKER and VOX Unit boards then down under the rear edge of the IF Unit to the Noise Blanker's "IN" and "GND" terminals. You do NOT have to lift the IF Unit, you simply connect the coax shield to the Noise Blanker Unit's "GND" terminal and the coax center conductor to the Noise Blanker Unit "IN" terminal.

This completes the IF out circuit addition to the TS-520. I made a short video showing the TS-520S IF OUT connected to the Heathkit HO-13 Ham Scan display.

Terry & Group,
Yes, I built mine and it might be my first SMD soldering experience. I remember that if I was starting on SMD project kits, I better purchase a good soldering iron, and I did. I bought the temp controlled Weller and assortment of tips, including some needle point styles for the SMD soldering. Also need a flux pen to flux the PCB, and some good quality tweezers. Also, need the thinnest diameter solder, like 0.015" or whatever is used for SMDs.
I also researched the internet and Youtube for info on how to solder SMDs, and I found a lot.
You need to do a lot of winding of small transformers and including stripping off the enamel coating. I found a solder pot works pretty good. By the way, MCM has all the stuff that I needed.
Yes, you can buy it in a kit or assembled.
Here's a link to the one I purchased:
http://fivedash.com/index.php?main_page=product_info&cPath=1&products_id=6
<http://fivedash.com/index.php?main_page=product_info&cPath=1&products_id=6>
You can built it in two ways; LF & HF, I built the HF, of course.

Or you can buy the assembled "Built" version
http://fivedash.com/index.php?main_page=product_info&cPath=2&products_id=8
<http://fivedash.com/index.php?main_page=product_info&cPath=2&products_id=8>

He maybe out of stock, so you need to keep stopping back to check .

Hi Everyone,

For those who want to try their hand at SMD work
this is a great way to start. There are a handful
of ICs to install plus some passive SMD
components. I would also recommend a 6 to 8 inch
illuminated magnifying glass to help ensure you
can easily see the solder joints.

WB5RVZ has excellent step by step construction
notes for the Ensemble receiver. The notes are
arranged so you can build and test a section at a
time. There are detailed instructions which help
you identify the components and where to place
them and a circuit diagram, graphic and
photographs to help you check your work. At the
end of each section there is a detailed test to
ensure you got everything right before you move on to the next step.

He also talks about required tools and directs
you to a couple of Youtube videos that describe SMD soldering techniques.

The notes can be found
here http://www.wb5rvz.org/ensemble_rx_ii/index?projectId=16

There's a great deal of satisfaction to be gained
from building your first SMD project.

Regards

Lou

I made 2 pictures and uploaded them to my website showing the rear panel's "IF OUT" socket and the coax connection to the Noise Blanker Unit "IN" terminal. The pictures are in "My Shack" link. Scroll down and you will see the 2 pictures

I also uploaded a short video showing the Heathkit HO-13 working with my TS-520S. I settled with a 500pf series capacitor since the HO-13 needs a little more IF signal level then a 100pf can provide. I do not have any experience with a Heathkit SB-620 or a Kenwood SM-220 with a BS-5 adapter installed. The SB-620 must be configured for 3.395Mhz IF frequency. If it's not then you may have a difficult time finding the components, especially the coil, to change it's IF operating frequency to 3.395Mhz. The video is located in the Video's link and in the TS-520, TS-820, TS-530, and TS-830 SG switch listing, titled "TS-520 and Heathkit HO-13 Ham Scan link.

The series capacitor is connected at the RCA "IF OUT" socket on the rear panel at the end of the RG-174 coax cable. The other end of the coax cable is connected to the Noise Blanker Unit's "IN" and "GND" terminals.

This addition/mod can be added in about 45 minutes to an hour depending on how good you are with a soldering pencil (no more than 30 watt soldering pencil!!!) and it can be removed in about 10 minutes and requires no additional alignment readjustments after installation or after removal.

Chris, I just got my 830S back from Dick W0NTA and he does very good work. My bandswitch was full of 30 years of tuner cleaner etc. Radio was a basket case trying to tune up on all bands. What a difference a clean bandswitch will make. His work is excellent and prices very reasonable. He will accept your whole radio or just the RF board which ever you choose.

I retired at the end of 2010 after working 27 years in the ham radio industry. We did 12 to 14 shows (hamfests) a year from coast to coast. IMO, the Orlando show is one of the best shows on the show circuit, and well managed. Plus, ou certainly can't beat the climate, especially for those exhibitors coming from areas of the country with cold temps and snow.

My experience with similar symptoms with the 520 have been the result of faulty relays. Mike is correct in pointing out the path through the relays as being suspect. The 520, 820 etc. are notorious for relay problems.

Some of the early production runs of the 520 had a problem with the trim pots. The ones located on the IF board and the AVR board seem to be the most troublesome.

Good luck,

KD8CN
Tim

If ESD hurt the 20 meter Ant LC tuned circuit it would have to hurt L41 Ant step-up and all bands would be down. It is unheard of for any of the individually switched in LC circuits to fail in service or to be damaged by ESD. Possible but very remote.

There is no 20 meter relay contact???

The TS830 schematic is readily available on variety of sources.

Lance,

If you use SEMI BREAK-IN CW, you will have to adjust the VOX DELAY to the transmitter remains keyed between dits and dahs and word spacing. IF you leave the VOX DELAY set fully CCW then there will be no delay between dits and dahs which is not good for the 520 control and T/R relays. To get around this you can simply flip the SEND switch UP in CW to transmit CW then flip the SEND switch DOWN when ready to receive. Most people use SEMI BREAK-IN CW and don't both with the SEND switch. VOX DELAY affect the DELAY in both CW and sideband so you can't set it for a delay period in CW and expect it to not affect the delay in sideband.

51100. TS520/TS520S NBI BPF Bandwidth

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-01-29 01:16:24 UTC
From: wagstw46@...
Topic: 51100 Message: 51100

Got around to sweeping the TS520 and 520S BPF at the input of the Noise Blanker at NBI and posted response curve in photo album. This is same location that KW places the filter in the TS820 and TS530/830 rigs to tighten up the passband. Unlike the filters in those radios the 520 series Hybrids employ a 3 pole top coupled resonator (T1, T2, T3).

To measure the bandwidth of the BPF I am inputting 3.395mhz tracking generator rf at NBI and looking at the output at gate of Q1/Q2. If you have a Sweep Gen both of these test points are very easy to access.

The bandwidth at the 3dB roll off is approx 54.5 khz which is just about twice the bandwidth of the later KW hybrid rigs. However still to tight to tap the IF downstream of this filter such as at NBO or the input to the SSB IF Xtal filter on the IF board for feeding your SoftRock Ensemble, RTL dongle, L-pan or other modern day panadapter.

I recommend that you do not attempt to adjust these transformers without a sweep generator or a spectrum analyzer. Especially important not to adjust T2. T2 sets the center frequency (Fc) of the filter. Might be able to adjust T3 for maximum RF voltage on O-scope or RF millivolt meter by measuring the voltage at the Gate of Q1 or Q2, but if radio seems to be working reasonably well I would not attempt adjustment without proper test gear.

I cant imagine not having enough signal level at NBI to feed your panadapter, but if you have problems could try peaking transformer T9 on the IF board.

Topic: 51102 Message: 51103

Scott,

If adjusting the DRIVE control in TUNE mode does not produce an ALC indication on any band then resistors R5 and R6, both are 56K 1/2 watt, on the HV Unit board are at fault. Replace both resistors with new metal film from Mouser

Mouser P/N - 660-MF1/2DCT52R5602D
Price each 22 cents

Also which model of TS-520 do you have? There are 3 models, TS-520, TS-520S, and TS-520SE. Look below the VFO knob, the model is in large letters and numbers.

Do you have the service manual for your TS-520 model? If not then you should download it and use it to service your KW hybrid. You can download the service manual, free, at my website

www.w5rkl.com

Click on the Manuals, Mods, and Docs link at the top of the page. When the Manual page comes up, scroll down to the TS-520 listing and click on the desired manual.

I assume you have the necessary electronic knowledge, test equipment including proper soldering station, and the necessary service manual for your TS-520 model. The model number is found directly below the VFO knob. When ever you refer to a TS-520 model you need to specify which one, there are 3 models of TS-520. If you do not have the service manual then you can download it free at my website

www.w5rkl.com

Click on the Manual link at the top of the page then scroll down to the TS-520 listing and click on the appropriate manual link for your TS-520 model.

Mark,
Is this rig new to you..or did this problem just happen?...Either way...take off the top cover and inspect the shaft and all the cogs and chain drives..see if anything is out of whack or cracked. While your in there...clean VC-1,2,& 3 with some good tuner cleaner/lube...DeOxit is a favorite. I do not use grease on the shaft or the ball bearings on on VC's. I use a light synthetic lube with teflon called "Super Lube" on the moving parts... 1 drop on the VC ball bearings...and one on the shaft supports...EXCEPT the VC wipers. This lube is non-staining, non-toxic, and dielectric, does not attract dust or dirt. I've had a 4 oz bottle for about 3 years..have used it on countless rigs and still have 3/4 bottle left. Try and steer away from a paraffin based lube...it gets gummy and attracts dust & dirt

Topic: 51109 Message: 51109

recently my meter (S , ip , power , alc etc.) behaves strange ,

after a transmission the meter should , after switching back to reception , more or less stay on
the lower end of the scale , e.g. receive signal indication (signal or just noise) ;
quite recently the meter deflects to Full scale a few seconds after a transmission and then return to normal
reception indication ; the weird thing is that this does not occur when connected to a dummyload !
has anyone experienced this phenomenon also ??
i'm using a HyEndFed antenna (i always use my dummyload first to tune my trx) ,
SWR is normal (1 : 1.2) reception is normal . Tuning is smooth.

any hints ere welcome ;-)

Tom,

First, the "ALC, IP, RF, and HV" meter switch position only work in
transmit which means the meter switch positions are disabled in receive.

Second, since the problem does not occur when your TS-520S is connected
to your dummy load, that leaves high level of noise/signals in your area
which is most likely causing this problem.

Just about anytime your panel meter deflects to full scale it is because it is not seeing the AGC or ALC bus (rail) voltage. It very seldom will lie to you. Only other way to get FSD in Rx mode would be for the AGC detector diodes to see a very strong off air signal at front end of receiver (something on order of -23dBm or more). Also if the Product Detector Carrier Injection Null is mis-adjusted. However, if due to Carrier null then should do it all the time.

The meter is a FET based reverse reading voltmeter. The Gate of the FET is monitoring either the AGC bus or the ALC bus voltage depending on whether in Rx or Tx mode. As the voltage goes down the meter goes up scale and if voltage is very low or missing the meter will peg FSD. The bus is normally at approx 3.2 vdc with RF gain pot full CW and no antenna connected. At FSD the bus voltage will be 1vdc or less.

It sounds to me like your Aux control relay contacts should be cleaned and make sure relay pins are cleaned and the relay fully seated in its socket for starters.

Now that being said it should make no difference if on the antenna or dummy load. Does it do it every time on the antenna? Does it do it intermittently on the antenna? Is it possible that you have just not caught it on the dummy load?

The other remote possibility is that the TIF amp, TX Mixer, and Driver tube bias is not switching properly and the very strong signal that the AGC detector diodes is seeing is your own internally generated TX rf output. This again would be due to bad/dirty contacts in the Aux control relay. As noted above should make no difference whether on Ant or Dummy load.

The fact that it only momentarily goes FSD and then comes back down and works properly as an S-meter with off air signals doesnt sound like it is an off air signal issue to me. Do you have another antenna you can try? How about switching off the SG switch and trying it on the antenna?

Jimmy:

I bought it on ebay from a seller named mdflyelectronics. I guess they also have their own website at mdfly.com although I have not visited that site.

I got five 500K trimpots, the kind that are little blue rectangles with the adjustment screw sticking out of the top. I guess one of them will do the job Okay. Total cost including shipping was $3.19.

Good Luck!

Hi Jimmy:

I dont know about Roberts trimmers but my guess is they will not be a direct replacement.

Almost 95% of the replacement trimmer pots I see mounted in KW hybrids are not the original carbon single turn pots. I believe these were made by Matsushita and have a 6mm pin spacing. Most if not all are linear taper.

I see some cobbled jobs were person extends the new trimmer pot pins with stranded hook up wire and the pot is laying loose on the top of other components. Some will extend with solid hook up wire and others will use bare tinned hook up wire with insulated sleeving on the extension lead wires. I even see a few that have been replaced with fixed resistors.

You have couple of options to replace with the original single turn trimmers:

1. Frequently search Ebay and use terms like NOS, Vintage, Carbon, Bakelite, Single turn, Trim, and/or Trimmer pots. Try using different combinations of these. There are a few trimmers listed as I type this. From time to time using these kinds of search terms will find exact replacements.

2. Contact Bob Mansker and see if he is willing to harvest from a board or buy the board from him and harvest yourself.

3. Google using similar search terms as noted in Step 1 and also try the CB repair parts websites and surplus electronic parts websites.

4. If serious about servicing hybrids for paying customers most economic approach is to start buying "Donor" rigs to provide you with a wide variety of parts that you can harvest to keep these treasures on the air. This way you wont have to pay Ebay prices for rigs that you see on there all the time being parted out. This is painful but if there are no "Donor" rigs then eventually wont be able to repair radio back to original form and function. I finally had to bite the bullet and start buying "Donor" rigs and stop thinking of them as parts rigs or tech specials as I use to think of them realizing that most if not all could be repaired and returned to service. You simply need donors so others may live!

Of course some parts can be remanufactured, but that is an expensive and time consuming venture and frankly not any money in it. We can be thankful that Greg NR6C spent a lot of time remanufacturing the Drive capacitor chain drive sprockets. I can assure people are not beating his door down and he isnt getting rich. Just a labor of love. Same for Ken K4EAA who makes the brass bandswitch couplers and the new RL-1 Aux Control relay for the 530/830 rigs (replaces the troublesome Omron 4PDT flat pack).

I have 830 here now that has a cracked Tank Capacitor plastic band position indicator. The clear pointer with red line on it. Fortunately I have couple of TS830 donor rigs and can harvest a new pointer for the customer. Trying to manufacturer one-off pointer would be time prohibitive and expensive.

If you should find a source of the original carbon single turn trimmers please post here for all of us.

Mike,
Using VOX for CW is a question that has been on my mind. I want to preserve the tender Kenwood relays but don't want to pound my final section either.

I've read your January 28 post on this subject but still not sure of what you are saying. So, if you wouldn't mind spelling it out for us hybrid newbies, I'm sure lots of us would benefit - full vs semi break-in vs Send switch on and impact to the radio of each in CW mode.

Many thanks for what you and guys like Terry, et al do for us to help keep these great radios alive and well. I've learned so much here in the past year and have done maintenance, repairs and improvements I never would have otherwise attempted.

Tom and others,

Semi Break-in uses the CW side tone to trip the VOX relay amp. The VOX DELAY determines how long the relay remain energized when tripped by the CW side tone. The VOX DELAY pot setting will be the same for CW as for sideband VOX. You cannot set the VOX DELAY for CW then a separate setting for side band VOX. What ever you set the VOX DELAY for CW, that same delay time will be used for sideband.

In CW mode the CW side tone is applied to the audio amplifier so you hear the dits and dahs in the speaker. At the same time the CW side tone is applied to the VOX circuit. If VOX is turned ON, pressing the CW key in CW mode will cause the VOX circuit to activate the VOX RELAY amp, energizing the relays, switching the radio from receive to transmit. Setting the VOX DELAY determines how long the relays remain energized. A very low setting of the VOX DELAY pot can result in "relay chatter", the relays energize when the side tone is applied to the VOX Circuit but the relays do not remain energizes very long, quite often less than a couple 100 ms. Therefore, when operating CW, set the VOX "ON", and send some dits or dahs while adjusting the VOX DELAY. Stop for a second or two and if the VOX DELAY pot is adjusted properly the relays should remain energized for approximately 2 to 3 seconds after stop sending dits or dahs.

The CW side tone has nothing to do with the Carrier Generator signal. A lot of hams think the CW side tone is actually transmitted which is not true!! The CW side tone performs 2 functions

1. To allow the operator to hear his/her dits and dahs in the speaker
2. To activate the VOX RELAY amp to energize the relays

Nothing more!!!

The 520 and it's VOX circuit and relays are not designed to operate full break-in.

Terry:

The trimmers I ordered are 10MM square and 5MM thick. The outer pin spacing is 2.5MM either side of the center pin, and the lead length is 6MM. I have no idea if they are linear taper or audio taper. Adjustment is on the "top" (opposite end to the leads) via a small screw.

I think that the trimmers will come pretty close to fitting the VR2 spot and the lead length should enable me to make them "bowlegged" if required.

I'll admit that I gave thought to drilling another hole in the side panel access area and adding a "meter adjustment" pot there....

In any case we will see, and I'll report back on my efforts.

Robert

You would need two pots. One for Zero VR-1 and one for Span VR-2.

Well hopefully they will fit.

I am always interested in finding original carbon single turn linear taper trimmer pots (preferably NOS) so I can restore customers radios to original config. Absent that I use harvested ones that I clean and test.

Date: 2015-02-01 19:42:04 UTC
From: Mark Gilger
Topic: 51123 Message: 51123

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by me, WB0IQK. There
were 21 stations checking in under good band conditions.

We had the following number of radios checking in.

3 running TS-520(x)
3 running TS-530(x)
4 running TS-820(x)
3 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

Jimmy was running my TS-830 + Drake L-4B amplifier.

The Sunday net was run by me, WB0IQK. There were
29 stations checking in under fair band
conditions. We had the following number of radios checking in.

5 running TS-520(x)
4 running TS-530(x)
1 running TS-820(x)
4 running TS-830S
1 running TS-510
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-940S + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome

as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total 142, Sunday☐s total = 88
December 2014, Saturday☐s net total 92, Sunday☐s total = 86
January 2015, Saturday☐s net total 110, Sunday☐s total = 84
February 2015, Saturday☐s net total 0, Sunday☐s total = 29 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net

Hi Terry ,

Tnx for the quick response to my e-mail !

I'll try cleaning the Aux control relay first ;
What part indication does the Aux control relay have ? (RL1 or RL2) I guess it's RL2 !?
Where is the Relay situated ? (near the choke coil at the bottom of the pcb ?)
can it easily be removed from its socket ?
I assume the housing of the relay can be brittle due to its age ......can it easily be removed for cleaning ??
what is the best approach for cleaning the relay ? (I do have a can with compressed Cleaner 601 by CRC industries for cleaning electronics)
what kind of cloth / paper can be used best ?

tnx in advance for your help ,

The 520S service manual shows the location of all the parts, including both relays. Figure 10 on page 38 gives the location of RL-1, underneath the VOX board; RL-2 is shown in figure 9, same page, right next to the final unit enclosure, very near the rectifier board.

Download the service manual, there are links and mentions of the location for them nearly every day on this board. If you cannot find the PDF files nor the links to them in the list archives, ask me off-list.

Relay contact cleaning is done VERY CAREFULLY with some paper (thin, stiff card stock works best) and a SMALL amount of contact cleaner.

DO NOT TRY TO BURNISH THE CONTACTS WITH EMERY or anything else more abrasive. Paper is plenty abrasive as it is.

Using a toothpick or something similar, apply a tiny droplet of the cleaner to each contact on the relay. (Decant the cleaner spray from the spray can into a small container, the cap of the can usually works if it is -absolutely clean-.)

While the droplet is still wet on the contacts, GENTLY slip the paper card in between the two halves of each contact and move it back and forth a bit. GENTLY. Don't bend the leaves of the switch armatures, they are spring-tensioned to very close tolerances.

Do not forget that they are double-throw relays, there are two contacts per section - relay energized, relay un-powered. Just toggle the relay closed with one finger while cleaning the other half of each contact.

You will probably see small black or grey streaks on the card, use a clean spot for each contact set.

GENTLY spray "canned air" onto the contacts to remove the cleaner liquid, and let the fumes dissipate. No need to make like a fire-hose with the spray air, a few short blasts from a small distance (several centimeters/inches) should do the trick. Too close with too strong a blow might bend something you'd rather not see bent.

I seem to recall someone on this list quite awhile back, who energized a newly-cleaned relay or switch without letting all the volatiles dissipate, and the small spark from a closing switch or relay contact caught the remaining cleaning fluid afire. Unpleasantness ensued, to be sure. It might have been another list, but which-ever group it was the

advice still holds. Don't burn your shack down with contact cleaner.

Use plenty care with any of that spray stuff; as well as being flammable, the volatiles and compounds from contact cleaners AND also from the "canned air" aren't good for you to breathe. Be certain to have plenty of ventilation when you use them.

Oh, and to be really thorough, POWER OFF, PLUG REMOVED FROM THE MAINS, and don't get across any capacitors, particular in the high-voltage circuits. Discharge them through a resistance (see 'chicken stick' in the list archives or a web search engine) before working on ANY of the parts of the radio. There are potentials inside which will flat KILL you. SK is forever....

Topic: 51109 Message: 51126

Tom,

The relays are located as follows:

1. Relay RL1 which controls the switch of the 520 between receive and transmit is located under the MARKER and VOX Unit boards, top left rear corner (see the TS-520 operator or service manual)

2. Relay RL2 which controls switching of the Xverter, the Meter, the linear amplifier relay, and antenna, is located below the chassis, next to the Final Unit inside a small metal enclosure (see TS-520 operator or service manual).

You can download a large one page high resolution schematic of the TS-520S on my website at the following link:

http://w5rkl.com/wp-content/uploads/2014/04/TS-520S_LARGE-Schematic_Hi-Res.pdf

Relay terminals "RL2-2" controls the switching of the meter but relay terminals RL1-1 controls the switching of the receiver's AGC and transmitter ALC gain control voltages that are applied to the IF Unit's "AGL" terminal to control the gain of the IF Unit.

Yes, the relay covers are fragile but if care is used, they can be removed to clean the contacts. Neither relay is sealed to prevent dust from entering the relays. I use a pointed tool to gently pry the sides so the plastic cover can be removed. Care should be used to prevent breaking/cracking the plastic covers.

I use small strips of copy/printer paper wet with contact cleaner, slid between the relay contacts. You will have to manually activate the relay armature to clean the normally open contacts so use care when performing this task as you can easily bend the relay terminals out of alignment.

Remove and clean one relay at a time. The control relay RL1 has a coil resistance of 385 ohms while relay RL2 has a coil resistance of 300 ohms. while they both have the same electrical and mechanical connections and they both will energized if swapped, do not swap the relays, RL1 385 ohm coil should be in RL1 socket below the MARKER and VOX Unit and RL2 300 ohm coil should be in RL2 socket inside the metal enclosure next to the Final Amplifier Unit.

When you have the relays out for cleaning, measure the relay terminal resistance in both energized and non-energized states. You can use two 6VDC lantern batteries wires in series for 12VDC to energize the relays. I have the Omron MH4P relay mechanical and electrical contact arrangements in a file on my website.

http://w5rkl.com/wp-content/uploads/2014/04/TS-520-MH4P-Relay.pdf

The file shows the bottom pins of both relays (they are the same except for coil resistance), the numbering of each pin, and the relay terminals mechanical/electrical positions in both non-energized (receive) and energized (transmit) state.

If you use an analog VTVM, set the resistance setting to "RX1", short the meter leads together and adjust the Ohms Adjust and Zero Adjust pots properly. The "Ohms Adjust" pot is adjusted so the meter points to the "INF" line on the top scale of the VTVM.

The Ohms Adjust pot is adjusted so the meter points to zero with the meter probes shorted.

Both pots will interact with each other so you will have to repeat the adjustment to ensure the meter points at INF with the probes NOT shorted together and zero with the probes shorted.

If you use a DVM/DMM, set the meter's function switch to the "200" ohm setting then short the meter probes together. Note the value displayed on the meter, typically it will not be zero but a very low resistance of less than 1 ohm or so. Most DVM/DMMs I have display between .9 and .7 ohms when the probes are shorted together with the function switch set to 200 ohms.

Next, measure each relay terminal connections with the relay not energized and note the resistance values.
Next, energize the relay (two 6VDC lantern batteries connected in series will provide a safe 12VDC source) and measure the energized pin connections.

The resistance values found in both energized and non-energized states should be equal to the DVM/DMM probe's resistance or zero on the VTVM Ohm meter scale. If any relay terminals show a higher resistance, repeat the cleaning process for the offending relay terminals again. I use small alligator jumpers to make the connections to the relay terminals, much easier than having to hold the relay in one hand and connect the ohm meter with the other. Same goes for connecting two 6VDC lantern batteries in series for 12VDC source voltage. Just be careful when cleaning the relay terminals to keep from bending the terminals. Use canned air to remove the cleaning and dirt/carbon residue.

Sorry Terry I didn't mean to take over or interfere with your comments but I just wanted to add a few comments for Tom about the relays since I've had experience with both of them.

Mike:

No problem whatsoever.

I often cannot continue as I am very busy here and probably should not be responding unless I see no one has responded to a request for help or I can amplify a little on what has been said or I see some bum dope being dispensed.

I am glad you mentioned about measuring the contact resistance to validate that the cleaning has been effective. New contacts would be in the 50 to 100 milliohm range and can almost never restore to that resistance by cleaning and most hams cant measure that level. About best you can hope to do is see the meter lead resistance as you mentioned.

Better way to test is use 6vdc battery and series resistor to limit current to approx 1amp and then measure the millivolt IR drop across the contact. Especially now that almost everyone has a DMM. Should see 100mv or less IR drop on a good contact. Now I wonder what would be the nearest standard value resistor you would use for the series resistor and "watt" wattage rating! Yes given the duty cycle of the testing might even be able to use something less than what the calcs would tell you. Just depends on your junk box.

I sometimes will resort to using a drop of full strength Deoxit DL-100 and when that doesnt work I do use a diamond burnishing tool. Cant hurt the contact any worse than it already is. If that doesnt work then have to rely on Bob Mansker for a harvested relay and hope it is in better shape than the one you are working on.

Please continue helping on this one.

Probably the 100th time it has been addressed but Tom doesnt know that. Glad there are good folks who dont mind telling and telling and telling!

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <w5rkl@...> wrote :

Tom,

The relays are located as follows:

1. Relay RL1 which controls the switch of the 520 between receive and transmit is located under the MARKER and VOX Unit boards, top left rear corner (see the TS-520 operator or service manual)

2. Relay RL2 which controls switching of the Xverter, the Meter, the linear amplifier relay, and antenna, is located below the chassis, next to the Final Unit inside a small metal enclosure (see TS-520 operator or service manual).

You can download a large one page high resolution schematic of the TS-520S on my website at the following link:

http://w5rkl.com/wp-content/uploads/2014/04/TS-520S_LARGE-Schematic_Hi-Res.pdf
http://w5rkl.com/wp-content/uploads/2014/04/TS-520S_LARGE-Schematic_Hi-Res.pdf

Relay terminals "RL2-2" controls the switching of the meter but relay terminals RL1-1 controls the switching of the receiver's AGC and transmitter ALC gain control voltages that are applied to the IF Unit's "AGL" terminal to control the gain of the IF Unit.

Yes, the relay covers are fragile but if care is used, they can be removed to clean the contacts. Neither relay is sealed to prevent dust from entering the relays. I use a pointed tool to gently pry the sides so the plastic cover can be removed. Care should be used to prevent breaking/cracking the plastic covers.

I use small strips of copy/printer paper wet with contact cleaner, slid between the relay contacts. You will have to manually activate the relay armature to clean the normally open contacts so use care when performing this task as you can easily bend the relay terminals out of alignment.

Remove and clean one relay at a time. The control relay RL1 has a coil resistance of 385 ohms while relay RL2 has a coil resistance of 300 ohms. while they both have the same electrical and mechanical connections and they both will energized if swapped, do not swap the relays, RL1 385 ohm coil should be in RL1 socket below the MARKER and VOX Unit and RL2 300 ohm coil should be in RL2 socket inside the metal enclosure next to the Final Amplifier Unit.

When you have the relays out for cleaning, measure the relay terminal resistance in both energized and non-energized states. You can use two 6VDC lantern batteries wires in series for 12VDC to energize the relays. I have the Omron MH4P relay mechanical and electrical contact arrangements in a file on my website.

http://w5rkl.com/wp-content/uploads/2014/04/TS-520-MH4P-Relay.pdf
http://w5rkl.com/wp-content/uploads/2014/04/TS-520-MH4P-Relay.pdf

The file shows the bottom pins of both relays (they are the same except for coil resistance), the numbering of each pin, and the relay terminals mechanical/electrical positions in both non-energized (receive) and energized (transmit) state.

If you use an analog VTVM, set the resistance setting to "RX1", short the meter leads together and adjust the Ohms Adjust and Zero Adjust pots properly. The "Ohms Adjust" pot is adjusted so the meter points to the "INF" line on the top scale of the VTVM.

The Ohms Adjust pot is adjusted so the meter points to zero with the meter probes shorted.

Both pots will interact with each other so you will have to repeat the adjustment to ensure the meter points at INF with the probes NOT shorted together and zero with the probes shorted.

If you use a DVM/DMM, set the meter's function switch to the "200" ohm setting then short the meter probes together. Note the value displayed on the meter, typically it will not be zero but a very low resistance of less than 1 ohm or so. Most DVM/DMMs I have display between .9 and .7 ohms when the probes are shorted together with the function switch set to 200 ohms.

Next, measure each relay terminal connections with the relay not energized and note the resistance values.

Next, energize the relay (two 6VDC lantern batteries connected in series will provide a safe 12VDC source) and measure the energized pin connections.

The resistance values found in both energized and non-energized states should be equal to the DVM/DMM probe's resistance or zero on the VTVM Ohm meter scale. If any relay terminals show a higher resistance, repeat the cleaning process for the offending relay terminals again. I use small alligator jumpers to make the connections to the relay terminals, much easier than having to hold the relay in one hand and connect the ohm meter with the other. Same goes for connecting two 6VDC lantern batteries in series for 12VDC source voltage. Just be careful when cleaning the relay terminals to keep from bending the terminals. Use canned air to remove the cleaning and dirt/carbon residue.

Sorry Terry I didn't mean to take over or interfere with your comments but I just wanted to add a few comments for Tom about the relays since I've had experience with both of them.

51128. Trio PS-515 good for TS-510?

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-02-02 19:40:04 UTC
From: dk3qn@...
Topic: 51128 Message: 51128

Good evening group,

I’ve just joined this group and would like to introduce myself first.

My first name is Klaus and I’m living near Munich, Bavaria, Germany.
I received my ham radio license and my call sign DK3QN in May of 1969
and over the years I’ve operated from various locations and with a
a lot of various ham radio receivers, transmitters, transceivers and
linear power amps.

Since the first days my main activities are focused around CW, QRP and
most recently 2m EME (now finished).

My initial reason for joining this group is my newly re-gained enthusiasm
for the older Trio/Kenwood gear. I've owned quite a number of Kenwood
rigs over the years and for the by far most part they very, very rarely let
me down.

Now, during this process, I’ve come across and bought 2 transceivers from

the old Trio/Kenwood days:

#1 is a TS-515 (6146 finals) with PS-515 power supply.
#2 is a TS-510 with separate VFO plus power cable, but no PSU (PS-510).

#2 is in a mint condition and I would like to get it operational.

Instead of just go-ahead with a trial-and-error approach and plug the
TS-510 into the PS-515 PSU, I’ve looked into both PSUs schematics, i.e.
the PS-510 and the PS-515.

Here is what I’ve found so far:

Connector pin assignment is the same.
Voltages are (almost) the same, except for the 190V resp. 210V line
DC voltage.

But: The PSU circuitry around R4 and R6 (PS-515) resp. R4, R5, R6 and R7
(PS-510) are different.

That is true both for resistance as well as wattage levels (much more wattage there
in the PS-510 PSU).
My assumption is, that because of the more tubes in the TS-510 vs. the TS-515,
14 tubes vs. 10 tubes, this voltage divider circuitry in the PS-510 is much higher
rated wattage-wise than in the more silicon-oriented TS-/PS-515.

It would be very helpful for me if somebody could give me his/her clues on this matter.
Thanks in advance!

73, Klaus, DK3QN

Terry,

I experimented with a 56 ohm 1/2 watt resistor in series with the relay terminals and a 5.28VDC lantern battery. I'm going to perform additional volt drop tests but the voltage drop across a series connected 55.8 ohm resistor is approximately 600mv. The battery is weak making it unreliable when measuring the contact voltage drop. The resistance of my DVM meter probes is .001 ohms when the probes are shorted together in the 200 ohm setting. The relay I used in the test has been thoroughly cleaned with contact cleaner. I should use the other relay that has not been cleaned. I also have a couple of relays that have the same contact orientation in either energized or non-energized states as the Omron MH4P relay is. I measured a couple of the contacts on one of the new relays and the contact resistance is well above the DVM meter probe resistance indicating the relay need a thorough cleaning. Those relays are "new" so as you said, new contacts can have high resistance!! I'll do more testing/measurements later on.

Mike

I think you had a typo and dropped the decimal and meant a 5.6 ohm resistor. Now you spoiled it. I had hoped you would have asked for new folks to submit to you how they would calculate its ohmic and wattage value! Looks like none of this Mike Ohms Law awards will be passed out on this one!

Yes you need stiff 6vdc supply. I use my bench supply, but couple of fresh 6v lantern batteries in parallel should work nicely. Duty cycle during testing is pretty low. One other place that can have a problem is even with new mini-grabbler or new alligator test leads. Common to find variations in resistance with them. Of course older ones can be all over the place.

I ordered a so called NOS MX2P relay off Ebay couple of weeks ago and it had high single and low double digit resistance across all the contacts. I never install any KW hybrid relay without either measuring resistance or doing the "6-1" millivolt drop test. Of course this is a must for any used pulls that you can find. As you mentioned these relays just have clear plastic dust covers and are not sealed so it is possible for the contacts to oxidize over the years having never been in service. I have read some app notes by Omron and others that talk about sulfur and chlorine in the atmosphere and adverse effect on contacts.

Some people clean relay contacts electrically, but I have never had much luck doing that. Idea is to apply high current and burn the oxidation off.

Tom:

Yes you can run without the Driver tube shield removed, but I would not. I probably see two or three per year with missing shields.

It isnt there because KW wanted to spend money that wasnt needed. Youve got about an 8 watt dc input Class A RF power amplifier sitting there in the open in close proximity to input and output LC tuned circuits. Like all tubes running Class A you have 360 degrees conduction so it will run hot. Feedback and isolation between stages is dependent on shielding. Same goes for the 3 spring metal ground straps on the 530/830 bandswitch shaft. That shaft penetrates the holes in the metal shield plates isolating the Driver and Mixer and Ant stages and acts like an antenna coupling RF between the stages. Anytime you cut holes in inter-stage shields you just defeated the shielding action. In old days we used special feedthru capacitors to make our lead interconnects and they even made grounding shaft bushings but kind of expensive. I see lots of rigs with at least one of these spring wire ground straps missing. Of course it causes me grief as I have to perform very careful visual to ensure missing one isnt laying inside the rig somewhere. Once found one laying on top the VFO under the Counter/Display board. Again KW didnt put them in to just spend money needlessly.

Easy to see effect of the 12BY7A Driver tube shield as follows;

1. Do your normal peaking of the ALC indication in Tune mode.
2. Set the ALC indication with the Car Level pot to some reference point on your panel meter perhaps full scale of the black printed ALC box.
3. Flip back to Standby and let tube rest a few seconds.
4. Flip to Send and monitor the ALC indication as you slide the black metal shield up and down over the tube.

What do you see?

There arent any real precautions other than realize you have Driver tube anode and screen grid voltages in very close proximity at the base of the tube around its socket directly below the Plate Load cap shaft coupler. I would clean the glass envelope of the Driver tube with alcohol. Then spread the shield can at its split with more opening at the bottom of the shield. You wont need a big gap and dont need a press fit. Then slide the shield over the tube making sure that that ground strap is inserted between the glass and the metal shield can. If too tight you can bend the ground strap or not seat the shield fully on the socket.

Mike

I re-read your post and see now that you probably are using a 56.0 ohm resistor to limit the current. That wont be enough current.

The reason you want 1 amp of current is the contacts are rated for at least that amount of current and with 1amp then 100mv = 100milliohms. No need for any calcs to convert mv IR drop to contact resistance. You know if you have 100mv drop or less the contact is good. 100 milliohms is pretty standard maximum resistance spec for relay contacts.

Look at Omron and Panasonic Relay Design App Notes and you can see the current ratings and the contact resistance specs and some will show the "6-1" test set up. Some manufacturers spec the contacts at no more than 100milliohms and others will be no more than 50milliohms. The MH4P and MX-2P data sheets are available on line.

Most of the circuits being switched in our KW hybrids are significantly less than an amp except for the NO contact in the Ant TR relay which at 100 watts into 50 ohm load is switching approx 1.4 rf amps.

Some people call this the "5-1" test and others call it the "6-1" test. Some would call it the "Kelvin or 4-wire" test employing two meters.

Of course can just use the resistance function of your DMM and make sure no resistance higher than the lead resistance.

Terry,

I still plan on performing additional test using different resistor values in series with the relay contacts. I have a couple of good 6 volt lantern batteries that I can wire in parallel for more current. I have a Pyramid variable DC supply but for now I'll stick with the lantern batteries. If the batteries don't work out then I'll switch to the Pyramid supply set to 12VDC.

The relays in my TS-520S have been thoroughly cleaned and the contacts measure the DMM's probe resistance. However, again, it's fun to do the other way too, using resistors and DC voltage and current to see the voltage drop across the contacts.

These are the simple experiments the inexperienced hams/members should be doing, "on their own", so they learn about voltage, current, and resistance, you know, good ole "Ohms Law" which is part of learning "Basic Electronics"!! Having said that, we can provide the information and instructions but it's up to the inexperienced member/hams to take the ball and run with it.

Mike:

Well it requires natural curiosity, thirst for knowledge, and always asking the "why" question. I think we both have a passion for it from our youth. Helps to have some aptitude but plain old hard work can accomplish a lot.

Lots of ways to skin a cat as they say.

Just about every step in the Service Manual can be accomplished by 3 or 4 different methods. I still remember many years ago when didnt have any test gear other than cheap pocket VOM using a general coverage receiver to listen to and adjust the carrier oscillators.

I dont like to say there is only One way or Never words. Some methods are just "good enough" while others are "best practice". Of course all the acceptance criteria have a plus/minus tolerance as do the components. A few adjustments even have an element of user preference.

Dont need lab grade test gear but I try to get all the Hybrids that come across my bench to meet or exceed the factory specs. I try to optimize the Rx and Tx performance. To do that requires a certain level of test gear and knowing how to use it. Sure makes it easier and faster. Of course it also helps if you have a point of reference. If you dont know what good performance looks like may settle for far less. I quite often write an owner about an operational issue to get back "I hadnt noticed". How can you not notice a VFO knob that rotates as if on an eccentric!

You can drive your car getting only 10 mpg fuel economy when factory spec is 26 mpg and unless you are a sophisticated driver/mechanic you might not notice any performance difference. Black soot/carbon deposits on exhaust pipe tips alone would be unacceptable to me!

Well same for these relay contacts. The as found resistance is often quite high yet on the surface doesnt seem to effect operation. It does if you can measure MDS for example.

I also like to find out how the design engineers test their devices. I learned about the "6-1" or "6V1A" relay contact testing method from reading relay App Notes.

Look at Pg 4 Item 10 for example:
https://www.panasonic-electric-works.com/eu-asset/en/downloads/ds_x61_en_relay_technical_information.pdf https://www.panasonic-electric-works.com/eu-asset/en/downloads/ds_x61_en_relay_technical_information.pdf

TS-530 Puzzler

Sent from Windows Mail

My ts-530 works great on all bands with full output except for 20 meters SSB. On this band the display goes dark and then blinks on and off when I transmit. Output drops to about 60-70 watts but it still transmits. My thinking is the band switch is dirty but not sure. Any thoughts are appreciated.

Tks,

Joe - N5XJT

More than likely vertical wafer switches on RF board. Some success can be had by cleaning wafer switches with small amount of deoxit and rotating band switch through its range, then good blowout with compressed air. report back if further advice required

Joe and Dave and Others:

Some clarifying questions might help the members understand your problem a little better.

1. You say radio transmits well with exception of 20 meters SSB. Do you mean you have no modulation in SSB mode? No modulation means no ALC indication on voice peaks and no indication on external wattmeter on voice peaks. Reminder you always load in CW mode and then place the radio in SSB mode and speak in the mic to modulate the radio.

2. When the display is blanking and then blinking on and off is that when you are modulating the radio in SSB mode with a microphone? OR When you are loading it in CW mode?

3. You say output drops to 60 to 70 watts but still transmits. If you have 60 to 70 watts output then YES the radio is transmitting at that moment. It just isnt transmitting to normal level of approx 100 watts output at approx 225ma plate current. I assume you are doing this loading and testing into a dummy load.

OR Do you mean that you can only load in CW mode to 60 to 70 watts output and then when you place rig in SSB mode it will modulate?

OR Do you mean when loading in CW mode the output drops from 100 watts to 60 to 70 watts? It is not possible to modulate the rig to 60 to 70 watts output in SSB mode unless you are whistling in the mic.

I suspect what you are telling us is that when loading the radio in CW mode (normal loading procedure) that you can get to approx 100 watts out at 225ma Ip, but the output power suddenly drops down to approx 60 to 70 watts and the digital display becomes erratic at the same time. Is this what you are seeing?

I will let Dave continue to run with this but just thought would help if we had a very good understanding of what you are doing when you see the erratic digital display and the output power dropping down to approx 60 to 70 watts.

Topic: 51140 Message: 51140

I have a acquired a TS-520SE. This is my first kenwood hybrid so I have
been doing a lot of research and web checking before sending this question.
The unit will tune up on the upper bands 21, 28, 28.5, 29.1 without any
issues and will output the 100w.
The lower bands, on the left side of the band switch, will not tune up at
all. I can set the drive and dip the plate in the tune and CW settings,
but have no output when I flip to CW, the load knob has no effect. This is
on the 1.8, 3.5, 7, and 14.
The receive seems to be fine on all bands..
On 21, LOAD set to minimum to start:
Tune: Meter ALC Drive peaks fine, Meter IP Plate Dips fine
CW: Plate Dips to 100mA, Power about *20 watts* output, Advance Load
(slowly through entire range) and power drops slightly, IP meter plate
stays at 100mA.
Does the same on USB and LSB

*On 7: Load set to minimum to start:*Tune: Meter ALC Drive peaks fine,
Meter IP Plate Dips fine
CW: Plate Dips to 100mA, Power about *5 watts* output, Advance Load (slowly
through entire range) and no change, power stays at 5w, IP meter plate
stays at 100mA.
Does the same on USB and LSB

*On 3.5: Load set to minimum to start:*Tune: Meter ALC Drive peaks fine,
Meter IP Plate Dips fine
CW: Plate Dips to 110mA, Power about *0 watts* output, Advance Load (slowly
through entire range) and no change, power stays at w, IP meter plate stays
at 110mA. The Max plate will go to 300mA.
Does the same on USB and LSB

*On 1.8: Load set to minimum to start:*Tune: Meter ALC Drive goes all the
way to lock, no peak, Meter IP Plate will not dip
tested no further on 1.8

All testing done into a dummy load.

Thanks for any assistance,
N4RCC - Richard

Richard,

On each band you state has problems, you end the band statement with:

"Does the same on USB and LSB"

What do you mean by that statement? How are you determining the same "20 watts" output is occurring on USB and LSB as it appears in CW mode? Are you saying when you talking into the microphone that the peak RF output you see on your watt meter is 20 watts?

Are you aware that when you tune the transmitter in TUNE mode that the final amplifier 6146 screen voltage is reduced by approximately 50%? This screen voltage reduction of approximately 50% also results in a reduction in final amplifier power output and IP meter indication.

Have you checked the transmitter's "DRIVER COIL ADJUSTMENT" that's found in the operator manual's alignment section?

Have you tried cleaning the band switch wafers, including the band switch wafers inside the final amplifier enclosure?

"What do you mean by that statement? How are you determining the same "20 watts" output is occurring on USB and LSB as it appears in CW mode? Are you saying when you talking into the microphone that the peak RF output you see on your watt meter is 20 watts?" Yes.. I switch from CW to USB and LSB and to see if there was any change in plate voltage, ability to load, and peak power output with modulation, and noted there was no change.

"Are you aware that when you tune the transmitter in TUNE mode that the final amplifier 6146 screen voltage is reduced by approximately 50%? This screen voltage reduction of approximately 50% also results in a reduction in final amplifier power output and IP meter indication." Yes..Just included for data and to show I was performing the tuning procedures on all bands so no one have to ask the question.

"Have you checked the transmitter's "DRIVER COIL ADJUSTMENT" that's found in the operator manual's alignment section?

Have you tried cleaning the band switch wafers, including the band switch wafers inside the final amplifier enclosure?" Not yet.. I do not have the proper tools to perform those actions...YET.
I also was hoping it might be a single component failure. Since All the upper frequencies,(21,28,28.5.29.1), tune up without issue and have good power output. So it would seem that the left side of the band switch, (1.8, 3.5, 7, 14) have something in common that the right side of the switch does not..
Of course I am trying to apply simple logic by observation which really does not mean much in electronics..lol

Hi Terry,
Tks for your response - good questions. In order here are answers:

Rig works normally on all bands, all modes except 20 meters. Output is 110 watts CW, slightly more in SSB, On 20 the display goes blank, then blinks on and off with modulation on SSB, both usb and lsb. . External watt meter (An AT-230 into a dummy load) shows approx. 60-70 watts with modulation. Rig tunes normally in tune mode and shows 110 watts on CW, the lesser output in USB. The display problem is not evident in CW or TUNE mode. The display blanks and then blinks on and off only in usb/lsb speaking into the mic. Changed mics, tried D-104 amplified, MC-50, and MC-85. Same with all. Again, this problem only occurs on 20 meters, rig works fine on other bands. The output occurs when whistling into the mic. On other bands the highest voice output is about 120 watts into a dummy load and whistling. I can tune/load the rig on 20 with normal output of about 35 watts in tune mode and 110 watts CW and no change in the display. Again, the problem only occurs when I speak or whistle into the mic in ssb modes. And to be a bit redundant, the problem does not occur on any other band.
Tks for considering,
Joe - N5XJT

Joe:

OK I need to let Dave run with this.

As I understand it you have erratic digital display and low RF output (60-70 watts)on 20 meters only when modulating in SSB mode and you see that lower level of output power when you whistle in the mic.

On all other bands when you speak in the mic in normal levels the display is steady and you see approx 25 to 30 watts on voice peaks. Also when you whistle in the mic you get nominal 100 watts output and the digital display remains stable.

L3 & L4 are the IF trap circuit. I suggest you try to get those slugs moving again. I use a little Deoxit and dab a drop down into the threaded hole of the inductor. It seems to penetrate pretty well and lube the threads.
Then do the best that you can trying to back out those slugs, trying the plastic tool first.....and then the last resort is a metal jeweler's screwdriver, but very gently. But don't do anything yet until the other guys speak.
Maybe you want to unsolder them and work on them in that way?

Dave,
Not an uncommon problem....but do not use a small metal "jewelers" screwdriver! You WILL crack/break the slug...and then..it will not come out! If using the correct sized tool in the slot on the slug will not get the slug to turn...there are several options...a small dab of super glue on the end of the tool..and then try and remove...heat the slug with a soldering pencil...then try and remove...but my preference is to desolder the offending item and using the correct tool from the BOTTOM SIDE...remove the slug and then using s small piece of waxed dental floss between the slug and the inside form of the "can" re-install the slug. The dental floss acts to take up space if the fit is sloppy/loose and the small amount of wax acts as a lubricant. I've done this probably 10-12 times. If I remember correctly...just like the 830 series..you can access the bottom of the RF board from the underside...by removing the AF/AVR board and the plate right below it.

Can anyone explain to me in basic terms how an SWR circuit works in the MFJ-949C. Below is the link to the schematic:

http://www.mfjenterprises.com/support/MFJ-949C/MFJ-949C.pdf
http://www.mfjenterprises.com/support/MFJ-949C/MFJ-949C.pdf

When I analyze the circuit it appears to me that the diode envelope detectors (1N34) should receive identical voltages with forward, reflected, or a combination of both power as both signals cross zero and change polarity in symmetrical fashion. It wouldn't be a very effective circuit if it functioned in this manner.

Thanks,

John

Dave,

I have cracked and broken lots of slugs over the years. There are a number of ways to remove, never with a metal object unless already broken. I use the direct heat method on these slugs, but if you over heat you can damage the plastic core. I clean tip of small solder it on and place directly onto slug. If you haven't done this before, less is more, meaning it may take several attempts to heat up. Once you have heat applied try and turn slug. Both ways, once you get it started you should be able to move without further application of heat. If you remove the slug altogether I would then apply some candle wax to thread for lube and also prevention of working loose.

Other method is to remove board an remove part from board for easier access. These methods are used by numerous techs.

John,

Run a google search for "swr bridge circuit" then
click on "images' just below the search bar.

You'll see they're all the same circuit. The MFJ
is almost an exact copy of the Drake W4 meter.

The current in the main line induces a current in
the core - it's a transformer. The current in
each leg of the secondary is 180 degrees out of
phase with respect to ground or common. Search
for Monimatch or bruen bridge in the QST archives
or even on Google for some detailed information.
You'll also find a similar circuit in almost every ARRL handbook.

John,

Note on the left the capacitive divider. It provides a sample of the voltage to both diodes – in phase.

The center tapped transformer samples the current and produces voltages at the two diodes – with a 180 degree phase difference.

Depending on which direction the current is flowing, the two samples add in one diode, and cancel in the other.

I assume the 0 – 10 pF capacitor is adjusted to provide a null in the reverse direction, by setting the two samples equal in amplitude.

http://www.mfjenterprises.com/support/MFJ-949C/MFJ-949C.pdf

When I analyze the circuit it appears to me that the diode envelope detectors (1N34) should receive identical voltages with forward, reflected, or a combination of both power as both signals cross zero and change polarity in symmetrical fashion. It wouldn't be a very effective circuit if it functioned in this manner.

Thanks,

John

51157. CAR level setting and ALC during tune-up

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-02-05 22:40:55 UTC
From: jwc123@...
Topic: 51157 Message: 51157

Greetings all,

A friend of mine brought over his TS-520S claiming the ALC was pinning the meter during tune-up. So I looked over the unit, made a few cleans and tweaks (switches and pots), and checked it all out. I did find the ALC was pretty sensitive during tune-up (250mA peak meter deflection with CAR = ~2). For the most part it tuned up fine and is working great and even had a nice QSO with a good audio report.

Thinking back I thought my 520SE was also sensitive so I proceeded to pull it off the shelf (I have several radio's 520, 520SE, 530, HW-xxx's etc.) and noticed it was sensitive but CAR=~3 for about the same meter deflection.

I didn't take a look at R5&6 on the HV unit and I don't think the problem is the T/R relay since everything does operate fine, just seems to not need much CAR level.

So my question is..... Is a CAR level of 2-3 about right for a 250mA peak meter movement when tuning up? Just want to see what's norm or if by coincidence both have the same issue.

Thanks and 73,

John kc9on

John:

Based on my experience with my TS-520 and TS-820S I think that a CAR setting of about 4 to 5 would be normal on 20M and below.. But 2 to 3 does not seem unreasonable.

Of course the required CAR setting will vary with the strength of the driver tube.

And of course, one thing I always seem to forget is that when going from 40M or 20M to 10M, you are going to have to crank up the CAR or Mike Gain control to a higher level to get the same RF output. All too often I'll go up to 10M, note the much lower output, get distressed over what's wrong with my radio - and then finally realize that I have not touched the CAR or Mike Gain control. Turning that up to maybe 6 or 7 brings the power output back to where it ought to be.

I have used the Super Glue technique myself - although not on my TS-520 and TS-820S yet. I used it on a Ten Tec kit that had slugs so loose that after a few trips up and down the interior of the coil the slug would no longer move. I ended up replacing the coils with new ones and I fixed the problem by taking a section of rubber and and using it to add to the resistance between the side of the coil form and the slug.

As for replacement slugs, I recommend never passing a trash pile that has on older model CB or even a Boom Box radio in it. I suppose you could even try buying new IF coils from a place like ALL ELECTRONICS just to get the slugs.

And has been mentioned, don't use metal screwdrivers on the slugs. And of course the plastic ones are too weak. So buy an assortment of wooden dowels, lop off a piece of a suitable sized one, and file one end to a chisel point. Then lop off the end of the chisel point to make it a bit more blunt. The dip the tool in varnish or superglue or something to make it harder. The great thing about that homemade tool is that it is less likely to break the slug while being strong than a plastic one, it costs next to nothing to make, and if you mess up the end you can just cut it off and file a new point on it.

While you are at it, take one of the larger dowels and made yourself a nonconductive tool for neutralizing the finals.

Good luck!

Robert

Neither R5/R6 or the Ant TR relay have anything to do with ALC indication.

Full scale ALC indication is a function of having proper operating bias voltage level (approx -55 to -60vdc) on the control grids of the 6146 Finals and no less than approx 47rms rf volts drive. If you have less than approx 39rms rf volts drive then you will have no ALC indication. Will have RF output but wont be able to peak the ALC indication with the Drive control. Will have to use a work around like peaking on receiver back ground noise or using the marker signal.

You need enough voltage swing on the positive going peak of the RF drive envelope to overcome the dc offset that the bias voltage presents. When that happens the control grid will be positive with respect to the cathode and a very small amount of grid current will flow (approx 35ua to 45ua) which will result in the ALC transistor driving the ALC bus voltage down causing the meter to drive up scale. KW uses this measuring of the ALC bus voltage to allow you to tune the Driver stage LC circuits to resonance. You are not setting a grid current level.

Having a high ALC meter indication with a low level of CAR pot injection is a good "problem" to have. Exception would be if you have pegged ALC indication the minute you crack the CAR pot off of full CCW position. If that happens you have bad BM diodes.

Remember none of the meter scales mean anything when peaking the ALC indication. All you are doing is tuning the Mixer and Drive coils to resonance so you have maximum RF voltage swing at control grids of the 6146 finals. That is how a Class AB1 grid driven linear amp works.

Look at the TX Level Diagram in the Service Manual and you will see that in a fully functional TS520 it only takes approx 0.20vdc at the BM to produce 100 watts output. That 0.20vdc should occur somewhere between #2 and #3 position. You can easily measure it for your rig at the BM wire wrap terminal post on the Gen board. Good idea to measure and record at each step for future use.

Now why it takes more CAR level opening on higher bands takes too many additional keystrokes and I have already succeeded in doing that.

Jan,
Yes, you are correct...that's why I only used THAT procedure ONCE...hihi. There are some "gel" type super glues...but I still prefer toremove the offending item and get at the tuning slug from the bottom. If the top part is chipped/broken, the other end I have found is usually just as new and I just swap ends and adjust to specs

> If that happens you have bad BM diodes.

In the interest of increased signal-to-noise ratio in the list, for the new fish, "BM" is "Balanced Modulator" the workings of which it does behoove you to study and understand.

That is, it helps you, IF you want to be a Ham of the other-than "I memorized the test bank and now I'm an EXTRA CLASS!! By the way, what's an 'Ohm'??" sort.

We're getting a lot of this kind of thing going on in my local area, folks who get their license (YAY!) without actually LEARNING ANYTHING about how things work and what radio really is (BOOOOO!).

(I've really and truly had a new memorized-the-test General Class license holder ask me what an "Ohm" was.... "Farad" and "Henry" drew blank stares, too.... Sad. Very sad.)

....
> Terry K9TW

Thank you, if no one else says it. Your long and detailed posts are a treasure. I archive ALL of your posts (and those of some others on the list), when you take the time to describe circuits and test techniques, repair procedures, and so forth.

I only WISH I could spend the time and get as familiar with this beautiful old machine (currently on my bench again...) as you have.

Subject: Re: [TS-520_820_530_830] Fwd: New to me TS520SE with Tx issue

"What do you mean by that statement? How are you determining the same"20 watts" output is occurring on USB and LSB as it appears in CWmode? Are you saying when you talking into the microphone that thepeak RF output you see on your watt meter is 20 watts?" Yes.. I switch from CW to USB and LSB and to see if there was any change in plate voltage, ability to load, and peak power output with modulation, and noted there was no change.

"Are you aware that when you tune the transmitter in TUNE mode thatthe final amplifier 6146 screen voltage is reduced by approximately50%? This screen voltage reduction of approximately 50% also resultsin a reduction in final amplifier power output and IP meterindication." Yes..Just included for data and to show I was performing the tuning procedures on all bands so no one have to ask the question.

"Have you checked the transmitter's "DRIVER COIL ADJUSTMENT" that'sfound in the operator manual's alignment section?

Have you tried cleaning the band switch wafers, including the bandswitch wafers inside the final amplifier enclosure?" Not yet.. I do not have the proper tools to perform those actions...YET.
I also was hoping it might be a single component failure. Since All the upper frequencies,(21,28,28.5.29.1), tune up without issue and have good power output. So it would seem that the left side of the band switch, (1.8, 3.5, 7, 14) have something in common that the right side of the switch does not..
Of course I am trying to apply simple logic by observation which really does not mean much in electronics..lol

Wes

Mike and I and few others are trying to elevate this forum to next level. We do that in couple of ways.
1. Always try to add a dose of basic electronics and practical RF communications fundamentals in addition to telling person to check the tune mode divider resistors.
2. Explaining how a circuit or function works ie how does a filter SSB transmitter work and what is a Balanced Modulator and what are its inputs and outputs and how it works. I should have spelled out Balanced Modulator. I have discussed BM hear more than once.

It is OK and the right place to come with operational problems, how to load, and accessory questions that have almost always been addressed numerous times over past years, but once you get past that and intend to be a long time KW Hybrid owner and do your own service work then time to start learning how the radio works. If you dont do that you will never be very good. Of course that starts with reading the circuit descriptions, studying the block diagram, and studying the schematic. No better time to learn how a particular circuit or function (like ALC indication) works than when you have a problem with it and come here for help with troubleshooting that issue. Just have to have the interest to take it to next level.

Unfortunately not easy to add more meat to the circuit description bones without a lot of keystrokes. At least I dont know how to do that.

I get lots of off forum requests for help. Other day a young fellow wrote about issue and said it was OK if I wanted to write a long response, but I didnt need to do that and OK to just send back the answer! I think a sign of the times.

John & other newer members,
A vast amount of information is accessible via this groups home page, and more than likely your problem has been discussed numerous times already.

You can click on "conversations" and then enter your subject in the rectangular box at the top of the page...and then click on "search groups." If for example you enter: "low output" you will get in return all conversations that have those key words in them...so figure 500+ or more. Be specific....ie "520S low power output" You will still get a good amount of information but it will be more specific. Or, go through the "files" section...lots of good stuff there too. Please spend some time looking thorough the various areas of this group to get familiar where you may find it, if needed in the future. Every msg/post has a unique serial number..that you can use later on..instead of killing a tree...hihi

  Thanks Terry and the group on the great explanations. One thing I did omit is where I was tuning up and it was on 40M & 80M. Looks like both rigs are working as good as they should.
I agree with the mini-tutorials on how/why it all works. It's a great benefit. I'm sure there are plenty out there that look at the 520 schematic and don't know where to begin. Notes like these get put inside my service manual because by next month I will have forgotten what to look for where and it might be a few years before I get back inside again.
I appreciate all the help and comments. Thanks again and 73

To Joe WB7UBQ..... Make your own DG-5 with the emulator that Stephan Leander (KV6O) designed.....Go to his web page (KV6O) and look..... Neat little unit... I love mine... You will find pictures of my build there as well(KD2DYY)..... MUCH more stable that the DG-5 unit and easy build. Stephen give you the SW to run...Price ir right and if you are ,at all, handy with soldering techniques you should have no problems with the build...Try it.....!

Best of 73's and good luck.

Mike (KD2DYY)Ps Thanks ,again, to Stephan for your GREAT work.....!

Do you know Stephan?

Do you think if he had a loaner TS820S that he would consider making a replacement for the DG-1? It uses the VCO (CVC), Carrier Osc (CCR), Clock Osc, and Bandswitch inputs to produce digital display.

I have several good TS820 rigs and would be interested in discussing possibilities with him.

Perhaps you could send him a copy of page 73 of the service manual that shows the block diagram. From that he might be able to tell if he had any interest in pursuing it?

Not sure what kind of market but I would think as much as there is for the 520 series.

Folks,
I did correspond with KV6O about using his DG-5 unit. The text is below. Anyone familiar with both the 520 and 820 who can comment on the comparison of the required take-offs?
Dave
KC3CIP

Thanks for the reply, Steve. The 820S has the DG-1 digital readout installed by the factor and uses BFO, VFO, and CAR signals from the radio. The 820 did not have the DG-1 display unit installed, but it could be purchased and installed as an option and, therefore, the 820 has the same take offs available.

I don’t know much about the 520, but it has many similarities with the 820, as the 820 succeeded it in the Kenwood model line. I’m going to share our conversation with the Kenwood 520_530_820_830 board. There are many experts there who are familiar with both rigs and perhaps can comment.

Subject: RE: DG-5 Emulator

Not sure since I don’t know how the internal display works in the 820, but if Kenwood did it the same way I don’t see why not. You’d need to look at the 820 schematic and compare it to the 520S (specifically, the BFO/VFO/CAR signals), and try tapping into those points on the 820.

Subject: DG-5 Emulator

Steve,
Really appreciate your work on the DG-5 emulator on your web site for use with the TS-520. I wonder if your unit can be used with the (also) venerable TS-820. Many folks (like me) love this radio, but problems with the DG-1 digital display unit are legion due mainly to poor soldering. Sometimes you can fix them and sometimes you can’t. I have been about 90% successful with my DG-1 on my 820S after many hours of work.

So, the question is can your unit be used with or adapted to the 820? I think there may be a lot of interest if it can be used or adapted for the 820.

Thanks and Best 73

The DG-1 Counter Mixer uses the external Carrier Osc (CCR) and the VCO (CVC) signals and a on board 1mhz clock oscillator, but does not use the VFO signal. The PLL uses the VFO signal, but not the DG-1.

BFO (Beat Frequency Oscillator) is another name for Carrier Insertion Oscillator (CIO) which is used as the LO (local oscillator) for the Product Detector which is just another mixer used to recover the audio from the IF. It is called a product detector because the outputs of the mixer are the audio and 2x the IF frequency which is filtered out by the Pi low pass filter at the output.

I dont know what signal levels are required to drive these new digital displays. I would think the VCO (CVC) would be sufficient as it is a nominal 1.0v rms or nearly 3 volts P-P. CCR is low as it is taken off after TC-1 trimmer on the IF board and is set for 50mv or 140mv P-P. It would be easy to tap off ahead of that at the CA2 level of 300mv or 850mv P-P. If not sufficient pretty easy to build a pre-amp.

I will see if I can contact the gentleman.

Terry K9TW

The TS-820, without the "S" suffix, did not come with a DG-1 digital display. The "DG-1" digital display was optional for the TS-820 which, when installed, made a non-S 820 an 820S.

The TS-820S came from the factory with the DG-1 digital display installed.

The DG-1 consist of the following units (see page 35 in the TS-820 operator's manual):

Display Unit (X54-1170-00)
5V AVR Unit (X43-1220-00)
Counter Assembly Unit (X60-1020-00)

The Display Unit consist of the display "tube" and connecting wires/plug assembly located behind the front panel and just above the VFO analog dial. The Display Unit plugs into the Counter Assembly Unit.

The Counter Assembly Unit is located to the left of the VFO. An edge connector below the chassis connects the Counter Assembly Unit to the PLL Unit, IF Unit, and receives +5VDC regulated power from the 5V AVR Unit and +14VDC from the AF AVR Unit. The front panel "DH" connects to the Counter Assembly.

The 5V AVR Unit is mounted on a tall metal hex standoff behind the Counter Assembly Unit and to the right of the IF Unit. The 5V AVR Unit receives +14VDC from the Rectifier Unit's "14" terminal through the power plug jumper between pins 8 and 9, and provides regulated +5VDC to the Counter Assembly Unit.

The Kenwood hybrid net on Sundays takes place on 14.316MHz @ 1800utc.

I suspect that your dipole cut for approx 15M(as you state) my be inadequate for the job if you are "asking" it to work on the 20M band.

From: Mark Gilger
Topic: 51185 Message: 51185

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by me, WB0IQK. There
were 20 stations checking in under good band conditions.

We had the following number of radios checking in.

2 running TS-520(x)
2 running TS-530(x)
6 running TS-820(x)
3 running TS-830S
0 running TS-510
0 running TS-511
1 running 599 twins
0 running TS-900

Jimmy was running my TS-830 + Drake L-4B amplifier.

The Sunday net was run by me, WB0IQK. There were
22 stations checking in under fair band
conditions. We had the following number of radios checking in.

6 running TS-520(x)
2 running TS-530(x)
1 running TS-820(x)
5 running TS-830S
1 running TS-510
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-940S + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome

as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total 142, Sunday☐s total = 88
December 2014, Saturday☐s net total 92, Sunday☐s total = 86
January 2015, Saturday☐s net total 110, Sunday☐s total = 84
February 2015, Saturday☐s net total 20, Sunday☐s total = 51 (Month to date)

This is where investing in an antenna theory book comes in handy.

A 15 meter dipole is too short to operate on 20 meters. The initial end to end length of a 15 meter dipole is approximately 22.04 feet at the center of the 15 meter band (21.225Mhz). The same initial end to end length of a 20 meter dipole is approximately 33.07 feet at the center of the 20 meter band (14.175Mhz). Note that the 15 meter dipole's initial end to end length is 12 feet shorter than the 20 meter initial end to end length!! The 15 meter antenna will not resonant on 20 meters which would result in high SWR and very poor performance!!!

The formula for calculating the "initial end to end length" of an HF dipole is

468 / <freq in Mhz>

The frequency of the center of the band is typically used for the value of <freq in Mhz>. This allows the dipole antenna to be used over the entire band without readjusting. This does not apply to 160 and 80 meter dipole antennas. The bandwidth of those bands is small, typically a maximum of 25Khz without readjusting the end lengths.

I use dipole antennas on 40 and 10 meters erected in an "inverted vee" fashion.

The 10 meter inverted vee was designed and built for 29.0Mhz, the AM segment of 10 meters. The RG-8x feed line length is close to 80 feet and the SWR is no higher than 1.2:1 over 100Khz of the band. The antenna is 30 feet above ground draped over a tree limb.

The 40 meter antenna was designed for 7.125Mhz with RG-8x feed length of 30 feet and SWR is 1.15:1 at the center of the band and no higher than 1.3:1 over the entire band.

The SWR meter percentage of error is typical, 10% of full scale. SWR meters are the Heathkit HM-102 and Drake MN-2000 tuner SWR. I do not use the tuner, only the SWR meter.

You do not have to spend a lot of money to build, adjust, and erect a good dipole antenna. Most of the materials needed can be found at your local hardware store. The wire can be lamp zip cord wire, speaker zip cord wire, auto hook up wire, insulated or not, even 3 conductor copper house wire can be used!!! The center and both end insulators of a wire antenna can be made from short lengths (4 inches long or so) of small diameter PVC pipe. I use RG-8x coax to feed all my wire antennas.

You can build the same dipole/inverted vee antennas but use 450 ohm feed line but you will need a tune designed to work with 450 ohm or 600 ohm feed line.

You can build a G5RV antenna that will work on all bands but it too will require a tuner. Most G5RV antennas use coax feeding the 450 ohm feed line. If you use a ready made G5RV with an SO-239 connector at the end of the 450 ohm feed line, do NOT cut the 450 ohm feed line!!! That section of the 450 ohm feed line is part of the antenna!!!

For best performance and maximum transfer of RF to the antenna, adjust the antenna to resonance (lowest SWR)!!

For more details on antennas and wire antennas you can build yourself and save money, I recommend you purchase an ARRL Handbook and study the chapters on antennas.

Remember, it's not the transmit power level that's important, it's the design and attention given to the overall performance of your antenna system that make the "real difference"!!!

Bub,
You can get a very detailed large format schematic from: n6wk "dot" com...under the Kenwood filles(free), I think Mike-w5rkl has the same on his site w5rkl"dot.com and Ken Kemski also has the large format ones too k4eaa"dot"com I know there are some others...but can not remember off the top of the head.

The large format schematics have lots of voltages...but some of the parts..ie the PLL and the counter unit do not. You will have to find a good SERVICE MANUAL to get the voltage points for them. Most of the large format schematics are high or very high resolution and can be enlarged for viewing on your computer screen without loss of resolution.
I took a thumb drive to my local Kinkos and had them print out the schematics for the 820 and 830 on a 36" x 17" paper...great for old tired eyes!

Maybe this question can be beat around here...if not someone please point me to another group for brainstorming...

I am using a Kenwood TS-820S for SSB and PSK31 on 10M, 15M, 20M and 40M. My setup is the TS-820S to MFJ-949e tuner to RG-58 coax to a 9:1 unun to an end-fed 53' long wire antenna. The antenna wire is 8' off the ground at the corner of the house and goes to a pine tree at the rear of the yard about 25' off the ground. I have dog bone insulators at each end of the antenna wire. Also a single 23 foot long 12 ga. wire for the counterpoise, 8' off the ground going away from the antenna wire.

Anytime I TX on 20 meter band, TV in the house shuts off and stereo pops loudly. TX on any other band does not affect it.

All my station equipment is grounded to a buss bar and a wire from the bar goes about 6 feet outside to it's own 8' copper grounding rod (not on house safety ground). Sandy, moist soil.

Scratching my head on this one. Like I said, if this is not the proper forum to help me troubleshoot this, I apologize. Thanks.

Jeff

You're right Joe, I have a high resolution TS-830 schematic on my website and it has voltage's shown on the schematic. The link to the file on my website is:

http://w5rkl.com/wp-content/uploads/2014/04/TS-830S-excellent-schematic.pdf

Also, Bub needs to spend time reading and studying the TS-830 operator and service manual's "Circuit Description" section.

Joe:

I have a dipole in my attic and when I transmit on 20M with my TS-820S via my MFJ-969 antenna tuner, I pop the GFIs in my bathrooms.

The way I look at it, those kinds of results mean that I'm really getting out!

I disagree with that statement. When I first installed my G5RVjr in the attic I was setting off alarm clocks, my transmit would lock up, my USB keyboard would drop off line so I could not log. Once I learn more about antenna (I'm not an expert) I fixed the issue so I don't interfere with any device.

I also have two antennas in the attic of a condo. a G5RVjr pointing north and south and a 20 meter dipole running east and west. The dipole works much better then the G5RV does but both do work. since I did not have enough room to run the dipole straight I had to make it into a invert "W" <=== up sidedown with glass insulators at the ^ and the W's. The antenna is cut for 20 meters and it is flat match on 20 meters and works perfectly on 15 meters. You can not make a short antenna longer so don't try it on 40 meters and trying to make it too short is not to efficient so it tunes on 10 but there is too much power loss to work the world.

Bottom line is if you have a good cut antenna, good grounds on the rig and tuner you should not be getting into any equipment around the house.

Hi Joe, sorry I have had the Flu for the last 7 days, too many drugs. I meant to say my dipole is a 20 meter dipole. It points east and west and it has a 1:1 with or without tuner but it seems to not be able to hear the current net control. It would have been nice to check in. Maybe conditions will change in the spring.

I live in a condo so I am limited on indoor attic space but I am doing well with contacts around the world on both 15 and 20 meters.

37 contacts since I got the old Kenwood on line and 13 confirmed states. Since I have only been in HF since winter started I am happy with how things are working (for now) :)

Still looking for any suggestions on this.. I have ordered the proper tools to perform the adjustments, should be in this coming week.

I asked this in the last post, but it may have been buried..so I will ask again,

Seeing that I am unable to load any of the lower bands (1.8, 3.5, 7, 14) that are on the left side of the band switch, but the right side (21, 28, 28.5, 29.1) of the band switch tunes up without any issues..Is there a common component that I can focus on that would affect bands 1.8, 3.5, 7, 14 bands that is not part of the other bands?

Thanks,
Richard N4RCC

It's likely propagation. I pretty much hear everybody on the 40 meter net but can only hear Mark occasionally on the 20m net on any of my antennas. Mark also notes that he turns the beam west to allow more western access to the Sunday net, if I'm not mistaken. I can often hear the folks out west, though, but not all of the eastern stations.

Bub,
As you can see the component(s) are labeled...ie Q4...R-1...etc
The SERVICE MANUAL has XRAY views of most of the boards..just have to take your time and locate the component(s) you want to measure. I can not offer any easy way...except to just get familiar with the inner workings and locations of each board and it's parts. Some of those boards are rather crowded and at times the letters or numbers may be partially obscured by another part. Get a real good bright flashlight and a magnifier

Thank you. I was wondering how to phrase that in such a manner as to avoid conflict. I'm a LOT too blunt, much too often, and the only way I could come up with to say it might have raised some hackles.

Starting with your post as a lead-in, here goes nothing.

NO, your QRM problems with your own equipment do NOT mean you are transferring useful power at the right frequency to the antennae of the people with whom you want to communicate.

What you are doing is transmitting out of band, wasting a good percentage of your radio frequency energy in the process. If it's hitting your own gear in the house, it's mucking with the neighbours as well, if you have any.

If you don't have anyone local to you, you're VERY lucky, because they aren't yelling at you for messing up their soap operas, or else calling Frank and the two Charlies about pulling your ticket for unresolved RFI....

You really need to figure out why the RF from your transmitter, feed line, and antenna is going out the way it is, and fix it. Not only will you stop overloading your other equipment with RF energy which it is probably not well-enough-designed to withstand, you very likely will start seeig an improvement in your radio contacts.

Once you clear this problem (and it IS a problem!) you will start putting that power to doing REAL work, and will make a lot more contacts in more places further away, once it isn't being wasted locally.

Start with the feed line, and see if there is any damage. (I'm guessing it's co-ax and not a balanced feed.) Check to see that water hasn't gotten INSIDE the coax sheath. That is not an uncommon occurrence. It is always a bad thing, though, and can cause no end of problems.

Bad connectors can also be the culprit; make sure they're all tight, not corroded, not allowing water into the co-ax, and so forth. The antenna itself is next, starting with the connection to the feed line. Check for frayed or half-broken wires, something metallic too close to the antenna itself, the ACTUAL - measured - length of the thing (vs. what you THINK it is) considering the frequencies at which you want to work; also whether there are traps in the system which might be off-resonance

and causing issues

Are you using an antenna tuner, and if so, why? Can you not load your antenna directly to the final tank of the Kenwood? If you can, do so and see if the problems with feeding into other gear in the house go away. Check the patch cable from the tuner to the radio, too. That short stub can cause more problems than you might imagine.

Simplify the whole system as much as possible. Check with a dummy load and see if you still get RFI into other devices. If so, then the problem lies in the transmitter itself. Check for loose grounds and missing case shields for a start.

If you don't spot and fix the problem yourself, your best option is to get a local Elmer in, some crusty Aulde Pharte perhaps from the local club. Take their help and their advice and see if things improve.

I cannot help but think that if you are having that much cross-feed into the appliances in your home, you must also be having excessive RF in your operating position. Non-ionizing to the side, heating your innards with RF energy can NOT be good for you.

Please get this resolved, it is in your best interest and that of anyone else living there.

51201. VFO issue with a TS-520SE

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-02-09 06:02:40 UTC
From: wayne.bowyer@...
Topic: 51201 Message: 51201

I just picked up a very nice 520SE at the Richmond, Va Frostfest Saturday. Very clean and lots of careful documentation included. All manuals (owner's and service manual) plus notes from owner each time he turned a screw. Only issue I can find is popping and scratching audio from the speaker when turning the VFO knob. Not everywhere on the dial but often. VFO is very smooth mechanically so it's not mechanical in nature (I suppose) Sounds much like a scratchy volume pot. Not certain where to start. I'm not afraid to get into it but not certain where to start as my last venture into a vfo assembly was when I built a HW-101 back in 1978.

Many thanks!

Wayne

Wayne,

Your problem appears to be a dirty VFO variable capacitor to frame flexible connection. This is not uncommon over time as the VFO is not hermetically sealed. The metal enclosure allows dust and corrosion to infect the shaft to frame flexible connection.

The VFO located directly behind the front panel has a small rectangle cover held to the VFO enclosure by 2 small Phillips head screws. Remove one and loosen the other which allows the panel to move so you have access to the variable capacitor flexible connection stated above.

Apply a small amount of DeoXit D5 to the connection point then rotate the VFO throughout it's travel in both direction a number of times. Wait 3 to 5 minutes before applying power. This procedure may need to be repeated before you clean the point sufficiently to eliminate the problem.

You will need some canned air found at Walmart's electronic department. The canned air comes in 2 different cans, a dark gray can or green can. They both are the same. Do not turn the canned air upside down or sideways when spraying as this will allow the propellent to come out. Do NOT shake the canned air can!!!! Give short burst of air applied directly at the variable capacitor's flexible point while rotating the VFO knob.

Be sure you read and adhere to the warnings on both cans, DeoXit D5 and canned air!!

If you do not have the service manual for the TS-520SE then you can use the TS-520S service manual. The TS-520SE is the same transceiver as the TS-520S but without the HEATER switch and the ability to use the DC to DC converter. The HEATER switch on the TS-520SE was replaced with a WIDE/NARROW CW filter switch. You also should have the operator's manual as well. You can download both of these manuals on my website. The TS-520SE abbreviated service manual link only has the parts lists and the schematic, it doesn't have any of the service chapters.

Hi Jeff,
I use 6 - 8 turns of Coax wrapped with a 6"id open center. This keeps stray RF off the feedline heading into the shack, I also have one about 6 ft from the tuner.

Been using this for years on all antennas that have a Coax feedline. Since I have been using them, I have never had an instance where stuff does not operate properly due to stray RF.

Give it a try. If is doesn't work, no harm done!
Oh... I would also check your ground connections for corrosion. Especially the one outside. (Just a thought)

Wayne,
I agree with Mike-w5rkl. DeOxit and canned air are the KW hybrid owner friends, especially if the rig is new to you and may have been sitting around unused for good period of time. If your rig had a DG-5..you may have also seen intermittent frequency display. On the 820S, 530S, and 830S the dirty VFO wiper is easy to spot as the digital display gets erratic at certain areas of the VFO travel and affects all bands. A note of caution however. If you plan on doing a partial or full alignment...inspect the tuning slugs of the OSC, MIXER, ANT, & DRIVE coils for cracks BEFORE you try and adjust them. Use a really bright light and a magnifying glass...and never...never use a metal tool to adjust them. You break them...they don't want to come out the the coil form...and more often than not...must be broken out...rendering them useless...they are real hard to find a replacement. Sorry to be a buzz-kill..just some real life advice...hihi

  Wayne,

Your problem appears to be a dirty VFO variable capacitor to frame flexible connection. This is not uncommon over time as the VFO is not hermetically sealed. The metal enclosure allows dust and corrosion to infect the shaft to frame flexible connection.

The VFO located directly behind the front panel has a small rectangle cover held to the VFO enclosure by 2 small Phillips head screws. Remove one and loosen the other which allows the panel to move so you have access to the variable capacitor flexible connection stated above.

Apply a small amount of DeoXit D5 to the connection point then rotate the VFO throughout it's travel in both direction a number of times. Wait 3 to 5 minutes before applying power. This procedure may need to be repeated before you clean the point sufficiently to eliminate the problem.

You will need some canned air found at Walmart's electronic department. The canned air comes in 2 different cans, a dark gray can or green can. They both are the same. Do not turn the canned air upside down or sideways when spraying as this will allow the propellent to come out. Do NOT shake the canned air can!!!! Give short burst of air applied directly

at the variable capacitor's flexible point while rotating the VFO knob.

Be sure you read and adhere to the warnings on both cans, DeoXit D5 and canned air!!

If you do not have the service manual for the TS-520SE then you can use the TS-520S service manual. The TS-520SE is the same transceiver as the TS-520S but without the HEATER switch and the ability to use the DC to DC converter. The HEATER switch on the TS-520SE was replaced with a WIDE/NARROW CW filter switch. You also should have the operator's manual as well. You can download both of these manuals on my website. The TS-520SE abbreviated service manual link only has the parts lists and the schematic, it doesn't have any of the service chapters.

Jeff:

I used to have a similar problem on 20 meters. Anytime I TXed on 20 meters it would blank out the TV in the house. Even running very low power of less than 100 watts caused the issue. I basically had to quit using 20 meters. Then I changed my antenna system. When I made the change in the antenna system I took down one of those telescoping push-up poles. When I took the push-up pole down my TVI issue went away.

At the top of each section of the push-up pole there is a fixed nut and a bolt. The bolt usually has a handle on it so that you can push the next section up and tighten the bolt to keep the section from sliding back down. That bolt holds the next section in place by applying pressure to the side of the section. It is basically a compression type connection. Well, where that bolt touches the metal section it forms a 'contact diode.' And it is able to rectify the RF that comes out of your 20 meter antenna and convert it to one of the frequencies that your TV uses for IF etc. Once I removed the push-up pole the problem was gone never to return.

I do not know if you have any push-up poles nearby but I would be very suspect that this is where your problem is coming from if you do.

Dan,

I mean no disrespect but you eliminated your TVI problem by changing
your antenna system, not by some non-sense idea a bolt on your
extendable pole was made into a contact diode that changed your 20 meter
transmitter frequency into a TV IF frequency that caused your TVI!!

I would love to know if those people who have so much trouble with a G5RV are using a tuner?
The designer himself always said that it was very preferable to use one, the original compromise feeder match was never that good. Also the match was originally to 75 Ohm BALANCED line NOT coax.
I use a single coil Z match which gives the required balanced output and OPEN WIRE feeders. This is VERY important, I have tried such things as 300 Ohm ribbon and they are hopeless.
This way I can get a 1:1 match on all bands and with careful use of the tuner was able to work Ecuador from NZ using a 1935 QST 2 tube receiver and the 820 as TX on 40.
It gives no problems at all with RF affecting other devices and I have quite a collection in my place.

51210. TS-520 Receive AGC question

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-02-10 00:32:15 UTC
From: Garry Nichols
Topic: 51210 Message: 51210

I have a TS-520 purchased new mid-1970s (S/N: 460218). On receive it has what I think might possibly be called AGC clipping which is obvious when listening to CW and can be heard on atmospheric noise peaks also (even ones that are not real loud).

I guess I might describe it as a kind of distorted "click" which is extremely brief. It can be heard at the beginning of each element that makes up a CW letter. It is not real loud and I think it has always sounded this way, but as I age it has become annoying to my ears.

Turning down the RF gain to the point where there is no S-meter movement eliminates this sound. Turning the AGC to "off" also eliminates it. It is most prominent with AGC on FAST and a bit less so on SLOW. The noise blanker is off for these conditions -- I seldom use it. Even when it is on the click is still present.

Does anyone know if this is a normal characteristic for this rig? I've scrutinized the circuit diagram but can see no adjustments for the receive AGC function and none are listed in the Operator's Manual or the Service Manual.

From: Lou Blasco
Topic: 51210 Message: 51211

Yes Garry,

Funny, I was thinking about that noise a couple
of days ago and made a mental note to ask the question here. You beat me to it.

I have a 520, 520S and 830 and they all have that
noise. It doesn't always grab my attention but if
I think to listen for it I can always find it.
I'm not a CW op but now that you mention it, it
is more obvious on good strong signals. I don't
hear it so much when I'm listening to mumblers or weaker signals.

I have done nothing to investigate its origin.

Mike:

I believe what Dan is talking about is what is known as the "Rusty Bolt Effect".

It is possible for metal junctions to form a "diode" which is a non-linear mixer that can re-radiate harmonics and can be a real source of RFI in your shack and I suspect a source of TVI back in the VHF television days that would be hard to diagnose and find. Utility pole line hardware and pole guy wires and associated hardware can be a source.

The ARRL has a good RFI handbook that discusses subjects like External Rectification, Re-radiation, and Rusty Bolt Effect. It can occur in metallic items in a strong rf field such as metal fence lines, in the joints of metal roof rain gutters, on guy wires and crosby clamps, and I have even heard of it occuring in antenna tower sections that have become corroded.

So I am not sure I would want to completely discount the joints of a push up mast especially if it was old and the galvanizing had deteriorated.

Thanks, Lou!

Do you notice that it goes away with AGC to OFF or reducing RF gain to a point where there is no S meter movement?

Can you hear it on static spikes also? Since atmospheric noise is full of minor spikes (and I don't mean the occasional static crash) it is a relatively steady presence. Seems like a steady series of extremely brief high pitched crackle. Each one almost too short in duration to even notice. But the rig sounds much better without it!

All this scepticism about unintentional diodes in corrosion in dissimilar metal contact, you'd think none of y'all had made an AM broadcast band receiver using a coil of wire on an oatmeal box, a razor blade stuck flat in a bar of soap, and a graphite pencil point on a bent safety pin.

What might you suppose the graphite and the razor blade are except a diode detector?? (If it's a 'coated' razor blade you can quite often dispense with the graphite and just use the safety pin point.)

Unintentional rectifiers are really real, and cause real RFI/TVI/QRM issues sometimes. The telescoping antenna pole story didn't surprise or bother me a bit. Sounds eminently probable as a noise source if it was inside an RF field of fair intensity.

Mike:

I can understand the skepticism. I had a hard time believing it myself. But, I had that pole up for many years and I had the TVI problem for all those years until I took the push-up pole down. I tried different antennas, I moved my TV and 20 meter antennas around to get them further apart, I tried Ferrite Cores and Beads, I tried Coax Traps on both the TV and my Ham Coax Lines, I installed a Low Pass Filter on my rig and a High Pass Filter on my TV. Nothing I tried worked. The day I took the push-up pole down the TVI was gone. I can even run my amp on 20 meters now. The push-up pole was the only constant through all the years. No, I can not prove it was the push-up pole but I just don't know what else it could have been.

No disrespect taken Mike. I always appreciate and respect your comments whether you agree or disagree.

Thanks

Well Jan you can poke fun if you want, but suggest you do some reading on "PIM" as well as "Rusty Bolt Effect". If we have any Cell Tower engineers among us they can describe the problems it causes them.

There are numerous resources on line in addition to ARRL in case you dont avail yourself of that wealth of knowledge and experience at your finger tips.

http://www.k5frc.org/training/RUSTY%20BOLT%20EFFECT.pdf
http://www.k5frc.org/training/RUSTY%20BOLT%20EFFECT.pdf

When am I ever going to learn to just keep my head down at the bench!

Besides who cares about VHF TVI these days when we all have cable or satellite TV. Heck 90% of our members never saw a Finco collinear !

I plan on going over the entire antenna system later this week. I have an idea, but will need to investigate further. My system was running fine until the cable TV installer showed up last week & installed cable. Today I inspected my coax running out of the eves to the unun and what do I find? The rocket scientist cable installer zip-tied his new TV cable to my counterpoise wire. I had to separate the two but still not happy with how close it is to the counterpoise. My counterpoise wire is a coated 12 ga solid wire. His new TV cable is RG-8.

51226. Passive Intermodulation (PIM)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-02-10 16:53:42 UTC
From: Jan Servaites
Topic: 51226 Message: 51226

If anyone is interested in Passive Intermodulation (PIM) here's some reading on the subject (from the people who make PIM analyizers to sniff this stuff out in the field):
http://downloadfile.anritsu.com/RefFiles/en-US/Products-Solutions/RF-Interference-Hunting-Techniques.pdf

The definition is:
PIM requires at least two strong signals and a non-linear device of some sort. Once generated, PIM frequencies are very predictable.

So, the two strong signals and the non-linear device (mixes the signals) to produce the intermodulation products.....which they say carries a predictable signature that can be detected and identified with a spectrum analyizer. So, one or some of the third, fifth, seventh (and so on) order intermodulation products could fall into a receiver's passband.

In the HF band, I don't see this as a serious problem, except down near the broadcast band, where there might be some strong AM stations nearby your receiver. I see the problem more in the UHF bands, where there are some serious high powered transmitters and their high gain antennas.

Tom & group,

Yes, that was an original KB-1 "spinner knob" that sold on Ebay for what....$175. Ken Kemski-k4eaa's excellent reproductions of the KB-1 knob sold for just about $100. These things where a virtual work of art! Ken spent untold hours on the machining and testing the anodizing to get them EXACT! He sold out quickly. It is currently unknown if Ken will run another batch

The reason I mentioned Passive Intermod was to get you thinking about how dissimilar metal or rusty metal junctions can form a "contact diode". I wasnt saying that Dans problem was PIM.

All you need on the HF bands to raise noise level in the shack and/or produce TVI is a "contact diode" and a strong RF field from a single source.

Many years ago I had an old Spaulding AX-48 riveted cross brace tower that caused my receiver in the shack to be near deaf due to rusty high resistance rivets on the X-bracing not to mention VHF TVI. Too long a story to present here, but I learned about "rusty bolt effect".

Of course first place to look is switching off breakers in your load center and then walk around the neighboring utility poles with your AM radio. When that produces no results then maybe time to think about "rusty bolt effect" or I guess today knock on neighbors doors and ask them to turn off the grow lamps!

I agree I am through.

From: dave.worfel@...
Topic: 51230 Message: 51230

I just purchased and added a VFO-230 to my TS-830S. I've found references to an internal battery in the VFO used to maintain memory state when power is removed. That said, I've been over the schematic of the 230 several times and have yet to find a battery. So my question is...does the VFO-230 have an internal battery? If it does where is it?

Back in the 1930's there was a thing in Europe called the "Luxemborg effect" this was caused by a very high power (around 200 KW) AM transmitter on the BC band actually modulating other BC signals by modifying the Ionosphere over Western Europe. But I doubt if many Hams, even in W/K run that much power and it is most effective around 1 to 1.5 MHz.

Jay,

You did not specify whether you have the TS-830 operator's manual or not. If you do not have the operator's manual then you should download it and spend time studying it before you attempt to operate the TS-830. You should also have a 50 ohm dummy load for testing. Tuning the transmitter into an antenna can cause intentional interference to other stations on the band(s). An antenna does not always present a resonant load to the transmitter but a 50 ohm dummy load does. An MFJ-260C 300 watt dummy load, $39.95, is a good test dummy load.

When problems of this nature occur, one should perform some preliminary check first which are as follows::

1. Check to ensure the rear panel SG switch is set to ON
2. Check the HEATER switch to ensure it's set to ON
3. Check for normal LSB or USB 60ma final amplifier idling current is present

You did not state whether or not you checked those steps.

How are you determining there is no RF output? Are you using TUNE and/or CW mode after tuning the transmitter up (transmitter tune up procedures are outlined in the operator's manual)? If you have the MODE switch set to either USB or LSB and you press the PTT button without speaking into the microphone, there will be no RF output.

Jay

Have a look on the rear panel at the sg switch. This may have been switched and preventing the tubes from working. Have you checked to see if the car Is not fully counter clockwise. Should not have to be much more than 10 o'clock position. Report back

51242. Re: [TS-520_820_530_830]

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-02-11 03:38:14 UTC
From: W5RKL
Topic: 51241 Message: 51242

The SG switch simply changes the polarity and source of the 6146 screen voltage which is "Positive" in the SG switch in the "ON" position or "Negative" with the SG switch in the "OFF" position. I explain how this happens in a video on my website.

If the SG switch is set to OFF, the operator can still achieve a peak ALC indication in TUNE mode because the negative DC voltage applied to the 6146 screen with the SG switch in the OFF position, only affects the electrons emitted from the cathode to the anode of the 6146. The electrons emitted to and flowing between the cathode and grid when the drive signal pushes the 6146 grids positive, are not affected.

Dear friends,
I have one TS 830s, but without power cord. It is with 12 pins.
I can find and buy one for TS 820. Can I use it for my 830?
Are they compatibile?

Tnx and 73

Sorry folks, sent it under wrong subject line. It should of course be
under transmit issues!
Must be more careful.

Hi Jay, As a relative newcomer here, I can recommend doing several searches of conversations where you search for the topics you are looking for. For you, you can search for "No transmitter output". Read all the replies from start to end. You will likely learn a ton about what to look for, where to find the information, and where to get various parts you might consider. It is very possible that you have no screen voltage. There are various protections for the high voltage circuits. It is possible that there might be some defective series resistors in the high voltage or screen voltages. Those resistors can fail and look OK. The comments will caution you about how to check these and not get shocked even with the power off.

You can download the operations and service manuals and schematic. You will see where you can purchase any protection components.

I have learned a TON of good information by just doing several conversation searches. The reason this is helpful is that it is quite likely there are conversations that cover your particular problem and save the experts to help with new and different problems.

73, Larry AJ6G

Almir,
The two are interchangeable, you must also make sure that the taps on the power transformer are correctly wired for your voltage. Also, make sure any internal jumper wires in the plug are correct. We do not often hear about an 830S with the removable power connection like the 820 here in America.

You can go to this web site: n6wk.com and look for the High Resolution TS-830S Service Manual. Go to the schematic towards the end, and on the left side of the page is a diagram for the plug showing wire diagram for 220V and 240V

Joe:

BZ-1 is a piezo-electric oscillator ie a Buzzer. With current it produces a Tone.

It has been awhile since I worked on a VFO-230 (kind of complex), but I believe the Buzzer tells the operator when the displayed Digital VFO Frequency has been stored in memory. You can see on the schematic that its keying transistor Q6 would have to get a High from the I/O Expander IC17 which would then bias on the transistor and allow current to flow to the Buzzer.

Owner operators of the VFO-230 should be able to tell us if they get a Tone when they input frequencies in to memory.

What I am telling you is what I believe and not what I know for certain and NO I no longer work on the VFO-230.

For those who are interested, I uploaded a copy ofSpring 1965 Elementary
Electronic. This copy of the magazine has an antenna article covering
basic antennas for the new ham.

The entire magazine can be downloaded from my website at the following link:

http://w5rkl.com/wp-content/uploads/2014/07/Elementary-Electronics-1965-Spring.pdf

The copy will download to your computer and open in Adobe Reader. Click
on the reader's page index text box and enter "89" then press "Enter".
Page 89 should display the first page of the article titled

"Antennas for the new amateur"

Ditto. Got any more? I knew I should have kept all those old magazines from when I was learning and making sparks and smoke. They're gold now, the mystery is gone perhaps (which was part of the enjoyment back then, for me anyway), but understanding the circuits at a look or two and being able to extrapolate to something I need now, that makes up for the loss of some fun.

A lot of the rest of the magazine is pretty useful, not just the antenna section. The Decibel, and Kirchoff's Law, for instance, and both articles on receivers. Some of the projects are useless these days ("The Boinger" - what a hoot), but the circuits might give someone an idea or two.

The ads are a hoot, too. Wish Lafayette was still open. I was sad when they closed their store here. Bits got a lot harder to find after that.....

The magazine article covering antenna basics for new hams is a good read/learning reference for those hams who do not understand antenna basics!! Hopefully some of the new ham members will take the time to download the magazine and spend time reading and studying the article so they learn.

If the ARRL Antenna Book is too much for them at this stage then one of the very best antenna primers I ever found was Ham Antenna Construction Projects by J.A. Stanley. Might get from used book sellers and/or Amazon?

It is a Sams Photofact Publication Cat No. HAJ-1. The 2nd printing was in 1965. Approx 160 pages. No math. Very practical book.

My copy is severely dog earred and I had to put clear packing tape on the spine!

Chapters:
1. Basic Horizontal Antennas
2. Basic Vertical Antennas
3. Using Antenna Test Equipment (simple test gear of that era)
4. Multiple Element Antennas (8JK, ZL-special, end fire arrays etc)
5. Vertical Beams (how to phase and electrically rotate them)
6. Compact and Indoor Transmitting Antennas
7. Long Wire Beams
8. VHF and UHF Antennas
9. Special Purpose Antennas (Multiband doublets, Windoms, Lattin, Folded Dipole, End Fed etc)

Another decent one is Simple Low Cost Wire Antennas for Radio Amateurs by William I. Orr W6SAI.

51256. Kenwood JR599 receiver BFO carrier X-tal

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-02-11 19:24:32 UTC
From: Behiels jean-Pierre
Topic: 51256 Message: 51256

Hi Kenwood members;

My Kenwood JR599 receiver doesn't work anymore in the LSB mode from the bandswitch setting.
I do have done some tests on the other bands and have also the same failure in LSB.
All other functions works good,perfect audio and receive sensitivity and so on...
I am quit sure the X-tal of the BFO carrier oscillator for LSB (3393.5Khz) HC6U type is out of his range !!
After a cool down from the rig,everything is working again(X-tal out of his range after warming up a whole day)
I will do a measure test tomorrow.
I like to buy a new one,but for this purpose I need the exact specifications of the X-tal befor I could make a order by my local dealer/costumer.
They make X-tals on demand but we have to now the correct specifications.
Could someone supply me the X-tal specifications of those X-tals in the JR599 ?
I do have take a look at de operating manual but nothing is specified yet ???
This X-tal stays on PB-unit C1214J at position X3 in the JR599.
I now that the X-tals in a old Kenwood TS510-TS515 and Heathkit HW101 are quit the same types ?

I look forward to receive some suggestions and info,please.

Kindly regards es 73's Jean ON4AEF.

Jean,

I don't know where you are going to buy a new crystal but I can say that INTERNATIONAL CRYSTALS, in Oklahoma City, OK U.S.A, charges $55 for one plus shipping and there's a 6 weeks lead time.

You might consider asking Bob Mansker, KE5FTF, if he has a TS-520 CAR UNIT board that has the LSB crystal still mounted on the board. The TS-520 CAR UNIT board use the same 3393.5Khz LSB crystal as the J599/R599 receiver does.

Bob's email address is ke5ftf at mail dot com.

I could be wrong but looking at the R599 and TS-520S schematics, it appears the TS-520 series CAR UNIT oscillator circuit is very similar to the J599/R599 receiver CAR UNIT oscillator plus the crystals themselves have the same type HC-6 holder with solder pins.

Terry:
I just tried my VFO-230 and don't get any tone when I add a new frequency into memory or if I try to add the same frequency twice. I've had my TS-830 and VFO-230 for roughly 30 years and don't recall ever hearing any tone when diddling with the VFO-230. A quick look through the operating manual makes no mention of any audible tone. Of course, I don't consider it a high value feature even if it did work.

If members are interested, back issues of Popular Electronics can be
downloaded free at the following link:

http://www.americanradiohistory.com/Popular-Electronics-Guide.htm

That website has other issues of old electronic magazines in pdf format
you can download free.

Have fun.

Hi Pete:

As I say just my interpretation from reviewing the schematic.

I am pretty confident that BZ-1 is a "buzzer" or tone oscillator. I went back and looked at the circuit again and Q6 is configured as an oscillator. That is why need 3 leads on BZ-1. I believe that the blue wire is the Feedback lead. Q6 is keyed by Q22 which is keyed by IC17. These things normally have pretty high resonant frequency so maybe your old ears cant hear it! Just kidding.

It would be interesting to tap 5vdc source momentarily on PB terminal on Conn 3 and power supply board ground.

KW included it to announce some function or operator action. It would make sense to me to tell the operator that he was successful in storing the digitally displayed frequency, but perhaps that is not what it is for especially since you say yours has never emitted a beep when storing a frequency. Of course could also go to IC17 and see if get a High at P53.

I dont know anything about the longevity of these devices. Maybe fragile and dont age well?

I never thought the operating manual had very much detail.

Not a big deal just trying to help Joe out with his "battery". He knew there was a device on the power supply board and it looked sorta like a battery.

Dave

Thanks that is kind of feedback I needed. Then I need to go back to drawing board to figure out what BZ-1 is used for.

Q6 looks like it gets its 5vdc thru Switch S10 MCH channel select switch. If Q6 or Q22 were bad then would still be able to load channels and not activate BZ-1.

If we had a brave soul could easily test BZ-1 to see if it is capable of emitting a tone. I suppose you guys are going to make me accept a VFO-230 for repair to satisfy my curiousity!

While you're in there diddling with the BZ-1, see if we can add a battery mod to keep the memories from going away every time I hit the main AC power switch that shuts off all AC power to the station. I've been thinking about that mod for 30 years and never get around to looking into it.

I am relatively new to this radio since I bought it off of eBay last year. Everything worked great until this weekend when I noticed that 10 meter just quit. No watts out, and no receive in. All other bands work fine.

Would anyone know what may have caused this to happen?

Hi Kenwood members;

My Kenwood JR599 receiver doesn't work anymore in the LSB mode from the bandswitch setting.
I do have done some tests on the other bands and have also the same failure in LSB.
All other functions works good,perfect audio and receive sensitivity and so on...
I am quit sure the X-tal of the BFO carrier oscillator for LSB (3393.5Khz) HC6U type is out of his range !!
After a cool down from the rig,everything is working again(X-tal out of his range after warming up a whole day)
I will do a measure test tomorrow.
I like to buy a new one,but for this purpose I need the exact specifications of the X-tal befor I could make a order by my local dealer/costumer.
They make X-tals on demand but we have to now the correct specifications.
Could someone supply me the X-tal specifications of those X-tals in the JR599 ?
I do have take a look at de operating manual but nothing is specified yet ???
This X-tal stays on PB-unit C1214J at position X3 in the JR599.
I now that the X-tals in a old Kenwood TS510-TS515 and Heathkit HW101 are quit the same types ?

I look forward to receive some suggestions and info,please.

Kindly regards es 73's Jean ON4AEF.

Dave;

I will appreciate that.

However, I have to tell you that if you and Pete have no "beep" tone when you input frequencies into a selected memory channels then your VFO-230s are not working per design.

I decided to look at the DFC-230 Operating Manual and Service Manual and it has virtually identical circuit. If you look at the Operating Manual on Pg 5 Item 8 it tells you that you will hear a tone when you enter frequencies in the memory channels. If you look at the Service Manual Step 11 it has you test the "buzzer" on each channel and tells you that expected test result at each channel is "Beep Tone Should Be Heard".

I am getting old but not that old. I can still read a schematic. Also I cant tell you fellows how many times I get back from long time owners of KW Hybrid transceivers that "I am the original owner or I have a pristine unit and it never worked that way" and some even insist that they talked to Kenwood and that is how it is supposed to work. I have to say with no joy that 99% of the time they are mistaken. Talking to a Kenwood design engineer in Japan is very different than talking to a tech on a service bench at a KW dealership.

If I owned a VFO-230 I would fix mine so it emitted a beep tone when I inputted into the memory. I looked at Pac Parts and they list NOS BZ-1 buzzers for $6.59. I would troubleshoot first to see if it was bad BZ-1 or transistor oscillator or switch. Maybe these buzzers age with temperature, humidity etc and fail?

Dave I will buy you a beer or two if I am wrong! Would not be the first time. Going to cost me plenty to meet you at your favorite pub!

From: rickou812@...
Topic: 51140 Message: 51274

I received my tools I ordered from Ken K4EAA and performed an alignment per the owners manual as suggested in an earlier post. All I managed to do was break the slug on the 28.5 oscillator, and of course it broke just a it went out of oscillation and will not turn back...

But other than that, the transceiver was pretty much in alignment on all bands. However, I still can not load the lower bands, 1.8, 3.5, 7, or 14. and now of course 28...due to the broken oscillation slug.

Is there any tricks to fix the slug enough to get it turn back up to oscillate?

And I ask again, is there a single component that would effect the lower bands, but not the upper.
I have not tried cleaning the band switch yet (other than moving it mutliple times through the different positions), but I would be surprised if the band switch would be the cause since the issue is effecting half of my bands and not the other half..

Any help is GREATLY appreciated,
Rick N4RCC

Thanks Mike;

For all your suggestions

A E-mail has been sent to Joe.

I already have obtained the specifications also :

HC-6 model

Capacitance 30pF

Frequency 3393.5Khz

Fundamental cut

Paralell resonant

Information for other guys on this reflector

www.ecoxtal.be

A local supplier can make all kind of X-tals on demand,but they need all those specifications.

Prices are quit payable hi ..

They already have delivered to me,for repair a old ham rig with CB X-tals on it hi

They supply quit everything you ask …

Someone else can tell you how to remove the core. Always inspect all cores to see if any cracked before you start. This is clue that they are most likely seized which is very very common with all the TS520 series hanging boards. Hard to describe feel and touch when attempting to tighten or loosen something. Alway good idea to apply small amount of WD-40 or even Deoxit with a sharp point toothpick to perimeter interface of the ferrite core and the cardboard former before you start in hopes that it will migrate down the threads.

There isnt any one common thing that you are looking for that I am aware of. I need more detail by what you mean when you say you "Cannot Load". Perhaps you have given it previously. Do you mean no ALC indication in Tune Mode on those bands or Do you mean you have ALC indication but no Ip or cant dip Ip either in Tune or CW modes?

I believe you said the receiver is working properly on all the low bands or as you say Left Side of band switch. Is that correct? Do you get approx S9 indication with the Marker on all those positions? If so then it tells you that the HET OSC is working which you need for both the RX and TX mixers.

Do you have a means to measure RF signal level voltages? If so, can find problem area in about 10 minutes. Need an O-scope, RF millivolt meter, or VTVM and RF probe(s). Study the TX Level Diagram to see what levels should be.

I would start by looking at the output of the TX Mixer on the RF board. This will be at MD or TP-1. You should measure something on order of 2 to 3 rms rf volts. If you do then you know you have TIF and HET (the LO) and the actual transmit signal is available at the Drain of Q1 for the input of the Driver Tube.

You can also go to the Control Grids of the 6146 final tubes at the tube socket and measure the RF drive level there. If anything less than approx 39rms rf volts then you will have no ALC indication but will have RF output power.

Are you certain that the bandswitch coupler is tight and has not slipped? (inside the shield can) If youu can select the proper receive band positions then not likely shafts have slipped.

What does the main RF Plate choke look like? Burned or discolored? Not likely fault.

Driver tube plate chokes L9 and L7 may have shorted turns. No way for you to tell unless could see that they are discolored. Very rare. See it more often on the TS530/TS830 with bad L36.

I uploaded the Summer 1964 edition of Elementary Electronics magazine to my website. The magazine can be downloaded free by clicking the following link. Clicking the link will download the magazine to your computer and launch Adode pdf reader.

http://w5rkl.com/wp-content/uploads/2014/07/Elementary-Electronics-1964-Summer.pdf

This edition of Elementary Electronics covers some of the basic subjects I have discussed and highly recommend to every inexperience ham to learn.

1. Basic Electricity (page 35)
2. Introduction to Vacuum tube Theory (page 51)
3. Basic Test Equipment (Page 67)

For those who think the vintage basic test equipment is useless, think again!! The test gear shown in the article may be old but it is very useful in today's ham shack as it was in the mid 60s. The basic test gear are excellent learning tools for the more advance test gear you will use later own.

Dave:

I forgot to ask. If you find that your new purchased VFO-230 has no memory beep tone would you be willing to remove the cover and take a look at the power supply unit board?

1. Confirm that BZ-1 is physically mounted.
2. Confirm that there is a jumper wire from Conn 3 Pin 7 PB terminal (PB = Buzzer Power?) to the junction of resistors R17 and R19 at Q6/BZ-1 tone oscillator.

The reason I ask this is that I took another look at the DFC-230 unit and note the BZ-1 is a 2-wire piezo buzzer and not a 3 wire buzzer as installed in the VFO-230. This is because they are using a 2 transistor oscillator and just using the BZ-1 buzzer as essentially a speaker and an not active part of the oscillator circuit.

The VFO-230 uses a 3 wire BZ-1 and its single transistor oscillator is configured as a Hartley using BZ-1 in place of the traditional tapped inductor. I am wondering if this configuration produces a more harsh tone from BZ-1 and that is why with the DFC-230 they modified the tone oscillator config to use a 2 lead wire BZ-1 buzzer and 2 transistor oscillator?

If so, perhaps KW disabled the tone oscillator function in the production VFO-230s by removing the jumper on the Power Supply unit that would feed the keyed supply voltage to the Q6/BZ-1 tone oscillator. If you find the jumper gone it would be interesting to temporarily connect it to hear what the tone sounds like? Understand if you would be reluctant to do that. If you blow it up I will buy it from you.

I am going to start shopping for air fare to VK land now or maybe tramp steamer passage would be more in my budget!

OK if it were there it would be on the Power Supply board unit. You can see it on the X-Ray view of the board. My guess is the empty spot is there unless they changed boards with later production runs.

OK as much as it hurts me I will eat large slice of Humble Pie. Nothing for you or Pete to fix.

According to the schematic it was designed to have a memory beep tone, but if no BZ-1 is installed pretty hard to have a tone.

Wonder if same with the DFC-230? Maybe the buzzers proved to be unreliable?

Thanks Dave for your help.

Dave;

I will appreciate that.

However, I have to tell you that if you and Pete have no "beep" tone when you input frequencies into a selected memory channels then your VFO-230s are not working per design.

I decided to look at the DFC-230 Operating Manual and Service Manual and it has virtually identical circuit. If you look at the Operating Manual on Pg 5 Item 8 it tells you that you will hear a tone when you enter frequencies in the memory channels. If you look at the Service Manual Step 11 it has you test the "buzzer" on each channel and tells you that expected test result at each channel is "Beep Tone Should Be Heard".

I am getting old but not that old. I can still read a schematic. Also I cant tell you fellows how many times I get back from long time owners of KW Hybrid transceivers that "I am the original owner or I have a pristine unit and it never worked that way" and some even insist that they talked to Kenwood and that is how it is supposed to work. I have to say

with no joy that 99% of the time they are mistaken. Talking to a Kenwood design engineer in Japan is very different than talking to a tech on a service bench at a KW dealership.

If I owned a VFO-230 I would fix mine so it emitted a beep tone when I inputted into the memory. I looked at Pac Parts and they list NOS BZ-1 buzzers for $6.59. I would troubleshoot first to see if it was bad BZ-1 or transistor oscillator or switch. Maybe these buzzers age with temperature, humidity etc and fail?

Dave I will buy you a beer or two if I am wrong! Would not be the first time. Going to cost me plenty to meet you at your favorite pub!

Maybe this question can be beat around here...if not someone please point me to another group for brainstorming...
I am using a Kenwood TS-820S for SSB and PSK31 on 10M, 15M, 20M and 40M. My setup is the TS-820S to MFJ-949e tuner to RG-58 coax to a 9:1 unun to an end-fed 53' long wire antenna. The antenna wire is 8' off the ground at the corner of the house and goes to a pine tree at the rear of the yard about 25' off the ground. I have dog bone insulators at each end of the antenna wire. Also a single 23 foot long 12 ga. wire for the counterpoise, 8' off the ground going away from the antenna wire.
Anytime I TX on 20 meter band, TV in the house shuts off and stereo pops loudly. TX on any other band does not affect it.
All my station equipment is grounded to a buss bar and a wire from the bar goes about 6 feet outside to it's own 8' copper grounding rod (not on house safety ground). Sandy, moist soil.
Scratching my head on this one. Like I said, if this is not the proper forum to help me troubleshoot this, I apologize. Thanks.

Hi Terry,

I had the 3 vfos open and did cross reference. I will look for the jumpers and see if they are there and report back. Was interesting to see the circuits had changes. One of the vfos works slightly different and has circuit changes I confirmed this is correct with vfo from same serial number batch, was only 100 numbers different based on serial number.

Well John 60 years of Amateur radio makes me very concerned for your rig. An antenna like that is bound to be a VERY bad match on one or more of those bands. I remember back in the 1950's when I used a long wire with inadequate matching and got a lot of RF burns even though I was running only 50 watts!
The whole antenna system has to be matched, preferably to a 50 Ohm load, which your Kenwood is designed to work into. The output tank circuit is not good at matching especially high impeadance loads.
This is why it is always a good idea to put together a simple ATU. Not only will your TX work better with less RF doing weird things in your home, but your reception will markedly improve. They are simple things to build (ideal for beginners) and there are lots of designs around.

Chad,

Does the hum also occur when using plain old PTT (set VOX switch to OFF)?

If so then the hum could easily be caused by improper ground wiring at
the microphone plug.

Microphone plug wiring:
Microphone Positive element to pin 1
Microphone sheild to pin 4

PTT switch wiring between pins 2 and 3

Dave:

If they have a different Power Supply Unit Board with no provision for BZ-1 then no point in looking for the jumper from Conn 3 PB terminal. I was trying to figure out the easiest way to disable the buzzer oscillator and removing the jumper looked pretty easy to me. I wonder if they have a revised Service Manual with the correct x-ray views of the boards?

As you know I am a KW hybrid lover but have to admit that the maintenance of the documentation was not their strong suit. They should have revised schematic, revised Xray views and removed the depiction of BZ-1 and associated transistor oscillator and its components. Unless there is a first production run unit out there that the as-built config matches the commonly available rev of the documentation that most of us work from. I remember working with Gordon N6WK off the List on more than one occasion on the VFO-230. It was a challenge for both of us.

Since no one currently has an operational issue with their VFO-230 we can end this thread now and move on to bigger fish.

As usual I appreciate your help.

Thanks for the help, I will try to answer your questions in this color below:

There isnt any one common thing that you are looking for that I am aware of. I need more detail by what you mean when you say you "Cannot Load". Perhaps you have given it previously. Do you mean no ALC indication in Tune Mode on those bands or Do you mean you have ALC indication but no Ip or cant dip Ip either in Tune or CW modes?
I can set the drive in tune, and dip the the ip in tune and CW, but unable to get any power out, turning up the "Load" does nothing on 1.9, 3.5, 7, and 14. while the tune procedure is(was) fine on 21, 28, 28.5, and 29.1, (was meaning before the broke the core in the 28.5 oscillator tuning coil) Of coarse still able to tune 21.

I believe you said the receiver is working properly on all the low bands or as you say Left Side of band switch. Is that correct? Do you get approx S9 indication with the Marker on all those positions? If so then it tells you that the HET OSC is working which you need for both the RX and TX mixers.
Yes that is correct. I should also note that I have a DG-5 and it displays the frequency correctly, which indicates it is receiving an HET, CAR, and VFO signal.

Do you have a means to measure RF signal level voltages? If so, can find problem area in about 10 minutes. Need an O-scope, RF millivolt meter, or VTVM and RF probe(s). Study the TX Level Diagram to see what levels should be.
Unfortunately, I do not have that equipment.

I would start by looking at the output of the TX Mixer on the RF board. This will be at MD or TP-1. You should measure something on order of 2 to 3 rms rf volts. If you do then you know you have TIF and HET (the LO) and the actual transmit signal is available at the Drain of Q1 for the input of the Driver Tube.

You can also go to the Control Grids of the 6146 final tubes at the tube socket and measure the RF drive level there. If anything less than approx 39rms rf volts then you will have no ALC indication but will have RF output power.

Are you certain that the bandswitch coupler is tight and has not slipped? (inside the shield can) If youu can select the proper receive band positions then not likely shafts have slipped.
Yes the band coupler is tight and looks good.

What does the main RF Plate choke look like? Burned or discolored? Not likely fault.
Looks good, no apparent discoloration or darkening.

Just to recap, the issue is no output on 1.8, 3.5, 7, and 14. Tune up procedure steps are all good until the point of adding load, or turning the load knob to increase lp, turning the "Load" knob does absolutely nothing on 1.8, 3.5, 7, and 14 and power output remains at less than 20w. Worked fine on 21, 28, 28.5, and 29.1 with a good 100w output achievable at lp of 200-220mA

Thanks for your help,
N4RCC - Rick

Klaus,

Yes, You can use the PS-515 to operate a TS-510. I have done that over here in the US with the PS-511 and the TS-510. The TS-515 / PS-515 is the European renaming of the TS-511 PS-511...for some reason Kenwood marketed the TS-511 in Europe as the TS-515.

I have also done it the other way around too, PS-510 powering a TS-511S.

I hope this helps...Good luck, they're both very nice old transceivers.

Rick :

OK good responses. That helps. So as I understand it you do have RF drive on the low bands as evidenced by fact that you can peak the ALC indication. If that is true it tells you on the low bands that the 6146 finals are seeing sufficient RF voltage swing and the problem then has to be from the 6146 plate circuit forward.

Here are some other suggestions: (Caution HV in the PA cage must discharge HV caps)

1. Look at the Plate Block/Coupling capacitor. It connects from the top of the RF plate choke in PA cage to the Plate Tuning Capacitor. It may be dark and discolored or even a hole blown in it. Capacitive reactance is inverse of frequency so it normally has higher "ac resistance" on the low bands. So if its capacitance has shifted very low it can offer much higher opposition at low frequencies. If you had a spare cap could temporarily bridge across it.

2. Look at Plate choke RF bypass capacitor at base of choke. It often cracks or has hole blown in it.

3. Look at the Plate Load air variable capacitor for couple of things:

A. Make sure the shaft coupler isnt slipping. Close the plates (fully meshed). Hold finger on plates and turn the knob and make sure cant turn the knob.

B. Close the plates and grasp the coupler and pull and push axially and make sure you cannot see any movement of the rotor and the plate spacing closing. The air variable cap has very close plate spacing. It is possible for the lock paint on the rotor lock screw on outboard end of the frame to back off. When that happens the plates short at some point in the rotation. Seen more commonly on TS530/830 caps.

One other thing comes to mind and that is bad fixed padder caps or the S5 bandswitch contacts are bad that switch them in on 160, 80, and 40. It would be very unusual to have all the low band padders to be bad or not being switched in. The padders with exception perhaps of 160 meters arent easy to see. Sometimes they will have hole blown in them. Here again is where test gear comes into play as you can look back with a digital LCR meter from the SO-239 and close the Ant TR relay contacts and measure the total capacitance and tell if the padders are being seen and correct value.

Lastly, if you plan on owning and maintaining and troubleshooting and repairing your own KW hybrid you will have to start building up a modest test bench. Heathkit level is just fine. Unfortunately visual and cleaning and wiggling and poking wont fix all the problems that you can encounter. Suggest you start looking for a VTVM and RF probe(s) as your first piece of test gear. You can search this site under Conversations and find numerous discussions on what pieces of test gear you need and what order to buy them in and even some discussion on how to use them. As I mentioned in matter of minutes we could determine state of RF drive levels at each key stage.

If anyone else has suggestion for Rick please feel free to contribute.

Mike,

Just want to thank you for these excellent articles.

I am working on getting my shack/workbench equipped with the vintage gear to work not only on my TS-520, but on other radios as well.

I have two Heathkit meters a VOM model MM1 (that does not actually have tube in it) and a VTVM model V-5 that has a tube.

Anyway, I want to make an RF probe for neutralizing new finals in my TS-520, and I was wondering if I can only use the V-5 VTVM for this, or would the MM1 VOM also work? Secondly, I was wondering if you ever saw this probe and if you know if it is a good one to make for this purpose? ;

Tom,

No you can't use your V5 VTVM without an RF probe to measure RF voltages when neutralizing the final amplifier in your Ts-520.

An RF probe simply rectifies the RF into a DC voltage. That rectified RF voltage is then applied to an displayed on the VTVM as a DC voltage. There's nothing mystical about an RF probe.

If you look at the TS-520 REL PWR meter circuit, you will notice a circuit that is similar to an RF probe. The diode in the REL PWR circuit does the same thing the diode(s) in an RF probe does, rectifies the RF from the TS-520 transmitter's output, into a DC voltage that is fed to the meter with the switch set to REL PWR.

I have viewed that website before. The RF probe schematics shown on that website, produce a "Positive" DC voltage to the VTVM. This is due to how the diode in the probe is connected to ground. If you notice the diode's Anode is connected to ground which produces a "Positive" DC voltage to the VTVM. Heathkit RF probes have the RF probe diode's Cathode connected to ground which produces a "negative" DC voltage that is applied to the VTVM. It doesn't matter which way the diode is connected, anode or cathode to ground, it simply determines which DC polarity setting you have to set the VTVM to. If you build an RF probe using the schematic shown on the webpage, you will have to set the VTVM's FUNCTION switch to measure "Positive" DC voltage. If you reverse the diode and connect the diode's Cathode to ground then you will set the VTVM to measure "Negative" DC voltage.

Heathkit made 2 RF probes that I am aware of, the PK-3 which has a maximum AC/RF voltage rating of 90 volts or less and a maximum DC voltage rating of 1KV and the 309C which has a maximum AC/RF voltage rating of 30 volts or less and a maximum DC voltage rating of 500VDC.

If you build an RF probe using the schematic found on the webpage you mentioned then I recommend using 1N191 germanium diodes which is the diode Heathkit used in their RF probes. If you use PVC pipe as stated on the webpage, I recommend you wrap the PVC pipe with aluminum tape then make a connection from the aluminum tape to the ground lead of the RF probe. The aluminum tape will act the same as the metal tube that housed the PK3 and 309C RF probe circuit in the Heathkit probes.

Mike:

Might I suggest that he not use the 1N191 diodes. I think Heath got a box car load of them back in the day. They are a fine diode (gold bond point contact) but NOS ones today can go for $10.00 each.

I would offer that he can use a 1N34, 1N60, 1N270 or even a Schottky like a 1N5711.

I have posted on this subject several times and provided this link as an aide couple of times.

Of course if you know of a source of 1N191 diodes then by all means use them. I am lucky to still have the original 1N191s in my 309C and PK-3 even after trying to kill them!

Terry is (as usual) right about the diodes. 1N34A's will work, but I used THREE iN4148 switching diodes, and a small slide switch scavenged from a mangled oscilloscope probe. If you need to measure lower RF voltages, you only need ONE diode in the probe. It will handle the PIV (Peak Inverse Voltage) presented by the RF you're needing to measure.

If you need to measure higher RF voltages (above fifty or so volts, IIRC, I'm sure someone here has the exact figures), and you use a single diode probe, you'll smoke the diode as soon as the probe tip makes contact with the live circuit. So you put three diodes in series, which triples the PIV rating.

I wanted ONE probe I didn't have to swap around on the meter, instead of one of each, so I added that little switch to the three-diode version I made (along the lines of http://www.norcalqrp.org/KI6DSrfprobe.htm), packed into a Sharpie marker shell. The switch simple shorts across two of the diodes in the string when closed, making the three-diode probe into a one-diode probe. Same resistor, same capacitor, same circuit all around; I just added the two diodes and the switch.

I'm thinking of putting a second switch (probably something to rotate instead of slide, to make sure I don't get the wrong one by mistake) to make the one-and-three RF probe into a straight-through non-RF probe. That way all three choices (RF 1, RF 3, and 'stock') of probe are all available without swapping wires on the meter.

Wes

The only thing about using silicon switching diodes is the barrier voltage is higher than germanium signal diode. With the 1N34 anything less than approx 250 mv wont register and probably anything less than approx 500mv to 600mv wont register on your single silicon diode probe switch position.

So what that means is wont be able to use it to look at TIF signal at the input of the TX Mixer on the RF board. Will work fine for output of the TX Mixer and of course the 3 silicon diodes will work on Plate of Driver Tube , DRV, and Control Grids of the finals.

No standard single diode RF probe with a germanium signal diode will be able to measure TIF at output of the IF board. Fortunately it doesnt often present a problem. When it does you need O-scope or RF millivolt meter to measure it as it runs in the 10mv to 50mv range level.

Wes

I forgot to mention you wont be able to measure or set Carrier Osc levels in most of the rigs at 300mv or VFO output level in the 530/830s that runs at 200mv. So not criticizing your choice of silicon barrier diodes for RF probes as long as you realize the limitations. You can go thru the service manuals and see all the levels that you need to measure which will help you spec needed rf voltmeter ranges.

I think if you look at the TS520S service manual (all the manuals for that matter) it will list the test equipment that KW used to align the radio and if you look under RF voltmeter will see they call for a meter that can measure 10mv to 300v rms rf volts.

So when we homebrew test gear need to ask self what will we use it on and what will its limitations be.

Similar to using your 3 diode probe to neutralize. You now have 3 silicon barrier junctions in series so about lowest it will register on would be 1.5v rf signal. That is fine for Plate of Driver Tube, DRV, Control grids of finals but not so good for neutralization. Your single silicon diode probe will let you null to approx 500mv level which is oK. Your O-scope and RF millivolt meters will let you null down into low double digit RF millivolt levels, but not necessary to be that precise.

Of course many people use a step attenuator and their bench receiver to neutralize on 10 meters and that works just fine in lieu of RF probe. Just have to be careful and not exceed wattage rating of the step attenuator.

Besides the things Terry mentioned, I would also inspect the vertically mounted tank coil (L4) on the ceramic form especially at both terminating end points and also at the switch connection points. This coil is used for 160 to 20 meters. A break at either end-point or bad solder connection will cause the tank coil not to do its job resulting in very low output.

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote :

Rick :

OK good responses. That helps. So as I understand it you do have RF drive on the low bands as evidenced by fact that you can peak the ALC indication. If that is true it tells you on the low bands that the 6146 finals are seeing sufficient RF voltage swing and the problem then has to be from the 6146 plate circuit forward.

Here are some other suggestions: (Caution HV in the PA cage must discharge HV caps)

1. Look at the Plate Block/Coupling capacitor. It connects from the top of the RF plate choke in PA cage to the Plate Tuning Capacitor. It may be dark and discolored or even a hole blown in it. Capacitive reactance is inverse of frequency so it normally has higher "ac resistance" on the low bands. So if its capacitance has shifted very low it can offer much higher opposition at low frequencies. If you had a spare cap could temporarily bridge across it.

2. Look at Plate choke RF bypass capacitor at base of choke. It often cracks or has hole blown in it.

3. Look at the Plate Load air variable capacitor for couple of things:

A. Make sure the shaft coupler isnt slipping. Close the plates (fully meshed). Hold finger on plates and turn the knob and make sure cant turn the knob.

B. Close the plates and grasp the coupler and pull and push axially and make sure you cannot see any movement of the rotor and the plate spacing closing. The air variable cap has very close plate spacing. It is possible for the lock paint on the rotor lock screw on outboard end of the frame to back off. When that happens the plates short at some point in the rotation. Seen more commonly on TS530/830 caps.

One other thing comes to mind and that is bad fixed padder caps or the S5 bandswitch contacts are bad that switch them in on 160, 80, and 40. It would be very unusual to have all the low band padders to be bad or not being switched in. The padders with exception perhaps of 160 meters arent easy to see. Sometimes they will have hole blown in them. Here again is where test gear comes into play as you can look back with a digital LCR meter from the SO-239 and close the Ant TR relay contacts and measure the total capacitance and tell if the padders are being seen and correct value.

Lastly, if you plan on owning and maintaining and troubleshooting and repairing your own KW hybrid you will have to start building up a modest test bench. Heathkit level is just fine. Unfortunately visual and cleaning and wiggling and poking wont fix all the problems that you can encounter. Suggest you start looking for a VTVM and RF probe(s) as your first piece of test gear. You can search this site under Conversations and find numerous discussions on what pieces of test gear you need and what order to buy them in and even some discussion on how to use them. As I mentioned in matter of minutes we could determine state of RF drive levels at each key stage.

If anyone else has suggestion for Rick please feel free to contribute.

Pete/Rick

VERY GOOD thought.

I have never seen that on the Tank coil but certainly possible. I have seen couple of times where the soldering wasnt bad at the Tank cap---it was non-existent ie totally missed at the factory! You wonder how a radio like that gets handed down from owner to owner and ever works right?

I can see where bad solder joint might eventually manifest itself over long time. There is about 3 amps of RF circ current so has to be some heating and cooling action going on.

Rick:

If you dont see anything obvious at the taps and end turns solder joints use a long insulated prod (dry wooden dowel rod will work) and tap on them as you slowly open the Plate Load cap and watch RF relative output or external wattmeter. Might start by gently tapping on the top perimeter of the ceramic former first. BE VERY CAREFUL as you are within reaching,falling, and touching distance of 900vdc plus at top of the RF plate choke, at the parasitic suppressors, and at the bakelite terminal strip near base of the choke. Dont reach across the top of the choke to do your tapping on the Tank coil. Come from the opposite side of the open PA cage.

Yes, the 1N191 diodes do appear to be rather expensive.

There are a couple of U.S. eBay sellers who are selling 1N34/34As but their price for a qty of "10" 1N34/34A diodes is rather high per diode. One is selling 10 for $8.99 plus $4 shipping. The other is selling 10 for $29.99 free shipping..

There's a Chinese eBay seller that is selling a qty of "50" 1N34/34A diodes for $5.99 "FREE" shipping which each diode cost 35 cents!!

Ok, you guys have convinced me to build TWO of these little RF probes. One RED one for higher voltages and checking RF circuits first. THEN a GREEN one with only one germanium diode for lower RF voltages once I know for sure it will not damage the probe. I will not build one single RF probe with a switch since it only takes one mistake to blow up the single diode. I want to keep it simple and not have to repair my test gear.

Since I am getting back into ham radio and now have a good TS-520 and a "parts" TS-520 that now works in receive (except for no Hetrodyne osc for 10 meters) and in transmit. I am installing the HV and screen protection parts. I have a bid on ebay for an RF signal generator and have ordered RF probes for a nice 100 MHz Tek scope I was given. I hope to use the signal generator to trouble shoot the missing osc. I will be looking for wiring or connection issues, a possible bad XTAL or switch issues (not sure that is likely since none of the three 10 mtr bands work).

Thanks for helping me get involved and getting these wonderful and useful rigs working to their best.

Joe:

Thanks Joe I was hoping someone would speak up.

Hybrid Restore is fully aware that the relay he is selling is not the Ant TR relay in the TS530S. This was discussed more than once when he was looking for a sub for the MX2P. Not sure why he does not correct his website.

Some owners claim that some TS530s came from the factory with a plug in Omron MX2P instead of the Fujitsu FBR 321DO12 PC board solder mount unit. I have only seen the FBR installed in a TS530 in two different packages. Clear case and black sealed case. I have an original FBR TS530 Ant TR relay complete with box and KW part number that I bought from Kenwood (California) probably 7 or 8 years ago).

We are all looking forward to Jans sub socket and relay specs being placed in our Files Section soon.

I shudder every time I get a TS530 on the bench as it is not easy and seldom long lived fix to clean the FBR relay contacts. See quite a few that the owners succeed in wrecking the relay. I then buy used pulls off eBay or Bob Mansker and install. Extra labor and not best course of action.

Jan:

The BAT-46 will work as will the 1N5711 or similar Schottky diodes. Couple of issues with the Schottky and that is the low forward voltage drop that you hear about typically only occurs at very low forward current (see the data sheets). At 10ma to 20ma forward current the forward voltage drop will approach closer to silicon barrier like the 1N4148 (around 0.4vdc) so wont produce as much dc output voltage for a given RF input voltage. In short wont be as sensitive as the germanium signal diode. So its use depends on the RF application.

Also the BAT46 has a junction capacitance of approx 10pf where the old 1N34 is around 1pf. So at higher frequencies the 1N34 would still be the diode of choice. Since we are measuring only up to 30mhz not an issue.

My thoughts are at the frequencies of the signals we are measuring in the KW Hybrids and the fact that our diode is looking at 10 to 11 meg ohm input impedance (low forward current) of our DMMs or VTVMs then either the Schottky or the Germanium signal diode will work just fine.

If you really want a sensitive signal diode you can use the trick that some crystal set builders employ and that is to forward bias the diode with battery and apply ua current to move the conduction point and now you can measure RF signal levels at lower mv levels. However, who wants to have to add a battery and sensitivity pot and remember to change the battery in their RF probe!

Go to Clifton Labs and look at his testing of RF probe diodes.

For anyone building RF probe use either 1N34 or 1N5711 or BAT-46 (although I have not personally seen any test data for the BAT-46 used in RF probe application).

Mel:

Yes you can use it if you are aware cant measure anything much lower than approx 400mv. So it would be OK for all the Tx levels from the output of TX Mixer to SO-239.

The BAV-21 is a switching diode that in addition to having a high PIV it has a much higher forward voltage drop (approx 1vdc) than a germanium or Schottky diode at typical ma forward current levels. Probably lowest RF signal level you could detect would be around 400mv. At that level might see slight upward needle deflection on 1.5 vdc range of a VTVM, but nothing you could accurately measure. Could read on DMM, but I prefer using analog for peaking and nulling.

Ken is using it to allow you to calculate RF power (100 watts) by measuring the peak RF voltage drop across the 50 ohm dummy load resistors with your DMM. He needed a high PIV rated diode for this as you will see approx 71rms RF volts across the dummy load. He used this single HV diode instead of a series string of 3 germanium signal or fast switching diodes which would give greater error from the three forward barriers in series.

I would not use it for a small signal RF probe diode. OK if you only want to measure things like RF drive levels at Plate of Driver Tube or at a Tee inserted at the SO-239.

Give it a try worse can happen is have to change it out.

Terry:
I opened up my VFO-230 today, removed aside the main board and got a good look at the power supply board. My board has the BZ-1 mounted on it. Not hard to miss; it's diameter is roughly the size of a half-dollar (roughly 1.25 to 1.5 inches diameter). With the cover off, I diddled with the memories, adding frequencies, etc. and at no time did the BZ-1 emit any sounds. And in reviewing the alignment procedures for the VFO-230, there is no mention to check for audible sounds, adjustments, etc.

Jody,
The rig in question is a TS-530S, not 520(S). The antenna relay of the 530S is not a plug in type. It is hardwired to the small circuit board next to the final amplifier board. The "other" relay aka RL-1 is on the IF board. It too is soldered/mounted directly to the circuit board and must be un-soldered for removal. The original relay is no longer available, but OMRON had a pin for pin replacement...and those are getting real hard to find. Ken Kemski-k4eaa has available a really well done replacement for that relay, using two modern small relays and a new mounting board.

Greetings group!
Busy, busy 2015 so far, many new members and some losses.
I just want to let the whole group know, especially NEW and/or MODERATED group members that there may be a significant delay in seeing your posts/msgs in the group msg area. For a little memory refreshment, NEW members are "moderated." This means that all your posts/msgs must be read and approved by a group co-owner/moderator, and either approved or rejected. At times, this is rather time consuming, especially now, since one of the group moderators has decided to move on. As you may or may not know, we're not here 24/7 - 365...but try hard to keep the traffic flowing. I am in the Pacific Northwest...so some of you are already up and moving 3 hours before me...and in the case of our European members 8+ hours, and are already posting before I even get up. The lost moderator was two hours ahead of me, so it worked out very good...he could take care of the morning rush...and I could deal with the later evening stuff.
Over the next few days, I will be watching for the more active group members that are moderated, and that show ability to follow the group policies..to be granted "unmoderated" status. That being said, IF the group policies are continually violated by an "unmoderated" group member, they will be put back on "moderation" and can wait for me to catch up with the review of moderated posts, This may take up to 24 hours or longer. I have a life too! hihi

If you have any comments or suggestions you want to share, send them to me OFF LIST. I will read every one.

Thanks for your understanding 73 Joe

51340. Hybrid Net Update (February 15, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-02-15 19:30:41 UTC
From: Mark Gilger
Topic: 51340 Message: 51340

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by Jimmy, WB2KNR There
were 22 stations checking in under good band conditions.

We had the following number of radios checking in.

2 running TS-520(x)
2 running TS-530(x)
6 running TS-820(x)
3 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

Jimmy was running my TS-830 + Drake L-4B amplifier.

The Sunday net was run by me, WB0IQK. There were
22 stations checking in under fair band
conditions. We had the following number of radios checking in.

2 running TS-520(x)
1 running TS-530(x)
1 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
1 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-940S + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome

as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total 142, Sunday☐s total = 88
December 2014, Saturday☐s net total 92, Sunday☐s total = 86
January 2015, Saturday☐s net total 110, Sunday☐s total = 84
February 2015, Saturday☐s net total 42, Sunday☐s total = 66 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Hi John,

Why not investigate how to make an RF probe? There was a discussion
about RF probes just a few days ago. The ARRL handbook will have some
info about it. You can google RF probe and find plenty of ideas. You
will of course need some kind of meter to read the output of the probe.

Regards

Lou

51343. TS-830S Dirty Band Switch

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-02-16 15:27:23 UTC
From: David Boothe
Topic: 51343 Message: 51343

Folks,

I thought I'd pass along some learnings I had when dealing with a problem in my recently-acquired TS-830S involving the importance of careful band switch cleaning when restoring an old rig.

I acquired the radio as an "e-Bay special" in December, along with a very nice MC-50 microphone 'throw in.' When it arrived the radio was in excellent physical shape inside and out, but I opened it up first and found the reason it was for sale: the band switch shaft coupler was completely broken inside the final cage.

I replaced the coupler with one of Ken's excellent brass units (K4EAA.com), being careful to align the shafts properly using some good guidance from Terry, K9TW. I sprayed and worked the pots and switches using DeOxit 5 and gave the rig a thorough visual inspection. No mods or other mischief noted except for the cut wire to enable the WARC bands.

I powered it up and receiver operation was excellent. The transmitter tuned well into a dummy load on all bands except 15 and 20 meters. On these bands, the tuning was unstable, with very touchy DRIVE adjustment (pegging the meter on ALC unless CARRIER adjust very low, say 1-2) and sometimes even quivering of the needle when trying to peak the DRIVE.

After peaking the DRIVE, I tried to dip the plate to tune up the amplifier and, after the plate current started to dip normally in TUNE mode, turning the PLATE control a little further would cause the plate current to fall off abruptly to near bottom scale. It would do this in TUNE and CW mode while trying to dip the plate. Final output power was very low after trying to tune this way-not much more than the driver tube would provide by itself.

I did a lot of troubleshooting to try and find out why only these two bands had a problem and, in desperation, decided to clean the band switch contacts again after looking at posts on this board. I carefully put CorrosionX (HybridRestore.com) on an artists brush and applied to the wipers on all band switch wafers on the RF board and inside the final cage. I worked the band switch MANY times after this. Bottom line, this resolved the tuning issues. The transmitter has tuned very well on 15 and 20 meters thereafter.

My theory is that my radio was put on the shelf after the band switch shaft coupler failed and stayed there for a number of years, resulting in the switches corroding in place after being in the same settings. This corrosion was pretty stubborn and didn't respond to my first shot of cleaning with DeOxit 5.

So, if you see output/tuning problems on some bands but not others, my advice would be to do a careful and thorough cleaning of all band switch

wafers before moving on to look for other causes. I thought I had done it, but didn't do a good enough job.

I recommend CorrosionX for this process, as it seems to work well for stubborn cases.

  Folks,I thought I'd pass along some learnings I had whendealing with a problem in my recently-acquired TS-830S involving the importanceof careful band switch cleaning when restoring an old rig. I acquired the radio as an "e-Bay special" inDecember, along with a very nice MC-50 microphone 'throw in.' Whenit arrived the radio was in excellent physical shape inside and out, but Iopened it up first and found the reason it was for sale: the band switchshaft coupler was completely broken inside the final cage. I replaced the coupler with one of Ken's excellentbrass units (K4EAA.com), being careful to align the shafts properly using some goodguidance from Terry, K9TW. I sprayed and worked the pots and switchesusing DeOxit 5 and gave the rig a thorough visual inspection. No mods orother mischief noted except for the cut wire to enable the WARC bands. I powered it up and receiver operation was excellent. The transmitter tuned well into a dummy load on all bands except 15 and 20meters. On these bands, the tuning was unstable, with very touchy DRIVEadjustment (pegging the meter on ALC unless CARRIER adjust very low, say 1-2)and sometimes even quivering of the needle when trying to peak the DRIVE. Hello All,
I just got a friends TS520S that has a rough feeling VFO. The unit supposedly works well otherwise.

As I rotate the VFO knob, it feels like it is steeping thru the rotation. Almost like it is detented. I looked inside & lightly lubed the gearset & bushings to no avail. Scissor gear function verified.

Then I saw the serrated knob/nut, looking in from the front panel sub dial plate side, and decided to see if I could turn it. It did turn & as I slowly turned it CCW the roughness went away. I am somewhat familiar with the 830S but the 520S is new to me. I did a search on 520S VFO repair & could not find anything, nor did I find a teardown of the VFO. I am assuming this knob/nut sets a preload that may have affected the feel of the gearset or even perhaps a bearing behind the nut.

If anyone has a good site to visit on this, please let me know.

Lastly, like many free jobs I do, there has been a little assignment creep. I was asked to check out low output after I told the owner the VFO is good. I verified it would only put out ~50W and so was about to swap the driver only to find I can’t get the tube out. It appears that the ground strip has grown to the tube shield. Anyone run into this? I don't want to clip it at the tube base. As I said, this is a free repair. I don’t want to send it back as a Receiver. Thanx – Bob W8RMV

51348. TS-520 AGC "attack" time constant

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-02-17 13:05:42 UTC
From: Garry Nichols
Topic: 51348 Message: 51348

Does anyone know which components set the "attack" time for the AGC in a TS-520?

Some time ago I had posted concerning a kind of distorted "click" that I hear at the beginning of a dot or dash and on the stream of spikes embedded in atmospheric noise.

It goes away with the AGC set to OFF or with the RF GAIN turned down to the point where there is no longer S-meter movement (effectively disabling AGC for signal levels below that point, I think).

It is not a pronounced sound, but it is annoying and progressively more so as signal strength increases.

WHY D-5 ???
It is ONLY 5% of the Active Ingredient...
I ONLY BUY, D-100.... 100% of what you NEED...
Why pay for 95% of Inactive Ingredients ???

Last Can of DeoxIt I purchased from " HOSA " a Company that caters to Musicians... It has a Metered Spray, not a Continuous Spray Can... Works for Me...

Glad to read of another Product available, but I think it is an Unfair Comparison... I would have liked to read a Comparison between D-100 and the other Product... Right now, it reads like comparing Apples to Oranges...

With DeoxIt, the Number following the "D" is the Percentage of Active Ingredient

Hey, Bill.
Thanks for the note. D5 was what I had on hand and has worked very well for pots, switches, etc. The can I have does have the metered spray, but still comes out pretty strong even on the “low” setting.

I wasn’t trying to compare the two—just reporting on what worked for me. I suspect that the difference was more related to cleaning technique than to the product itself.

Seems like both products would have a place on the bench!

John,
Folks say a VTVM is optimal because you can see the analog meter deflection when neutralizing for a minimum (using an RF probe, of course). Nevertheless, I use my digital multi-meter (10 megohms/volt) with an RF probe (Ramsey RF1) and have no problem neutralizing to a minimum (milli-) voltage across the dummy load.

I recommend he build or buy a W2IHY iBox not just
for this microphone but for any others. You can
then use line level from a simple mixer to drive whatever radio you want.

http://www.w2ihy.com/ibox-kit.html

I use exactly this setup with the same mic and always get good audio reports.

OK gang, here goes....
I have a Kenwood TS830S, love this radio!
The other day was on SSB and got a disturbing report. My audio going was awful. It has always been excellent. The way it was put to me was it sounded like really heavy 'arctic flutter', which is not outside the realm of possibility considering my QTH. Another way it was described was 'warbly'. Did a check and only putting out about 40W FM. Hmmmmm
Checked all my connections and mic, all good. Tried a different rig into the system using the 830's cabling, all good.
Earlier fixed/replaced the band switch coupling, that isn't it.
Checked/replaced all 3 tubes, same results so that isn't it.
I have exhausted my, admittedly meagre, skill set.

Thoughts?

Thanks de VY1MAB

Hi Steve,

Yes that will work but you need to be real careful with your levels as your mixer puts out way too much level for the radio if you're not careful. I would also consider the iBox because it has transformer coupling to prevent hum loops and limit the possibility of RF getting back in through the microphone. Once you add an attenuator on the line out you can get a nice audio balance that's easy to control.

Take a look here for advice on setting up your transmitter audio. http://www.nu9n.com/tx.html I'm not interested in ESSB but I think this guy's advice is very good. I've followed the level adjustments which are plain common sense and the results are as advertised.

Good luck with you setup.

Off topic, but lots of smart Kenwood folks here.

I could use some advice on my TS-130S. It has very low output, 10 watts on 20 meters, 30 watts top on 40-meters. If someone is very familiar with this radio to point me in the right direction I'll tear into it and see what's what. Otherwise it works fine.

I don't see a TS-130S Yahoo Group, if there is one I'd like to know. Love this fine old radio. So simple. I'll get this one going, then tackle my TS-830S that has not been on the air in quite some time.

Interesting, Brian. I didn't notice any appreciable difference compared to

the tuning rate of my 830S. The tuning rate for each is 25 kHz per turn and this is the same as the VFO-230 and -240. All are faster than the 820S, which is 20 kHz per turn.

This sounds like what was described to me as "motorboating" on my TS-520SE's SSB and CW signals. It was caused by the failure of at least one of the two high power filter capacitors, if I have the terminology right. A common problem and easy fix if that is indeed the problem!

I purchased a TS 520S from a deceased estate and as with ALL radios I get it went on my Variac. Brought it up to 40v AC and nothing, but when I touched the case my earth leak detector tripped just after I got a little boot touching the case. A check with a multimeter showed the case live at 40v AC. Taking the covers off showed what might be the cause, a HV Cap has the arse blown out, but the radio is in need of FULL inspection.
If I didn't have a Variac and plugged it straight to 240v AC and touched case????????? Well you get the picture.
ALWAYS with new gear to your shack use a VARIAC, it could save your life. I own a 15amp job. Money well spent I say

Very good advice. Even more, it's a swell idea to inspect a "new to you" radio for blown caps, burnt resistors, fried wiring, charred chassis scars, etc. before applying any voltage at all.

I restore more antique radios than "modern" gear so minute inspection and recapping is usually done before I even plug in a radio for the first time. Startling explosions, flaming power resistors and a couple of nasty "bites" encouraged adoption of that practice decades ago.

Congrats on the new 520 project. It'll be fun.

73,

Craig

VERY good advice Craig. I too restore vintage radio equipment for museums and individuals. One of the worst traps I ever came across was a big tuner/amp unit, it had a 2 wire power cord but the phase wire was wired to the chassis via a capacitor. Of course it had gone leaky!!!
A
Variac is every useful, as is a proper isolating transformer. But a good inspection is the best thing to start with in any event.

What I have used and it does work really good for vintage radios from the 1920s to the 30s is a gas welding tip cleaner. The kit comes is all different sizes so finding the right size for cleaning the socket should not be a problem. This is how I do it and you have to be very careful. I find the right size of tip for the socket, not to big about the same size as the tube pin. Cut off the blank tip so all you have is the cutting rod. I then dip it in Deoxit and run the rod down and up one time in each pin hole and then clean the socket out with denatured alcohol. Some contacts are so pitted that you may have to do this more than once. Use a magnifier glass to check your work.

Just a suggestion.

I measured the original 530 relay's resistance to be about 216 ohms; The replacement relay is slightly lower 185 ohms, so it loads the circuit down a little more, I would think.
The main thing, that I was searching for, is the right size physical size and socket combination that fits within the tight constraints within the 530. There is NO cutting necessary and it's all bolt in, which is really nice.

There is a VERY OLD BUT interesting video on youtube by N4DA that describes how to bring relays contacts back to life but it only addresses the receive side. A TS-430 is used as example but the theory pretty much applies to similar circuits. The video is over an hour long so you'll have to fast forward to that part if you do not want to view the whole thing. This is the same guy that worked my TS-950 a few years back and I just happen to find his video a few days ago while looking for TS-830 repair info. Also, I may have some of those relays left. The big question is where did I store them. I'll look around to see if I get lucky and find them.

51384. Adding a wide/narrow filter switch for CW

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-02-22 22:48:19 UTC
From: zehrhj@...
Topic: 51384 Message: 51384

I recently acquired a TS-820 with digital display. It was in nice condition but the display was wacky. After re-soldering many of the connections on the display board, and creating some new hole-through connections for several of the ground traces, it is up and running.

The one thing I didn’t like was that on CW, only the narrow CW filter was available. I prefer to listen with the wider SSB filter and select the narrow filter when needed.

There is a suggested modification to install a switch floating around the internet. It is a bit cryptic, though. Here is one site listing it:
http://www.radiomods.co.nz/kenwood/kenwoodts820.html
http://www.radiomods.co.nz/kenwood/kenwoodts820.html

Also, an earlier posting on this group noted a suggested modification from 73 Magazine in April, 1980 (though I didn’t discover that until I was done and the scan of the magazine isn’t very sharp.).

The mod on the website listed above seems to suggest accessing the wires at the Mode switch. Those are very tight quarters, however. It is easier to access them at the 3-pin connector block on the IF board. With the rig bottom up, front facing you, this is on the right side near the back. There are three wires: grey, green and purple. The grey is the for the CW filter, going to the Mode switch. The green is the SSB filter going to the Mode switch. (Filters are selected by applying voltage through these lines.)

For the CW filter in/out switch, I used the DL switch on the front panel (though some use the Fixed Channel switch). Disconnect the black and white wires from the DL switch and leave them disconnected. Thread a three-wire cable from that switch down through the hole near the Mode switch and back along the bottom cable harness to the 3-wire connector on the IF board.

Cut the grey wire near the connector on the IF board. The section of the grey wire coming from the front (Mode switch) will go to the center pole of your switch. The other grey wire, from the board connector, goes to one side of the switch.

Tap into the green wire (you don’t need to cut it) and run that to the other side of the switch.

This is easier to understand if you look at the Operating Manual, Fig 12, p. 26. (Also in the Service Manual, on page 54 or 55 is this schematic in larger size). At the top right edge of the schematic you can see the connector blocks. The connector involved here is the second unit down. The block in the diagram has 5 pins because you position the three-connector block on the 5-pin connector according to what filter configuration you are using (see Fig. 25, p. 34, of the Operating Manual).

For my ears, the TS-820 is now more cw-friendly.

I'm new to the group - very pleased to be part of this community.

Howard K4LXY

51385. Dbu to Microvolt, or Dbm conversion

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-02-23 00:33:58 UTC
From: kevin_lemon@...
Topic: 51385 Message: 51385

I have been beating my head against a wall to try and figure out how to convert the Dbu signal levels specified in Japanese manuals to the Dbm or microvolt levels specified on my HP and Marconi RF Signal Generators.
I see that 0dbu is equal to .775volts, and so is 0dbm into a 600ohm load.

But my one manual says to inject a 30dbu signal into the antenna, and there is no way I'm injecting the 24.5 volts that I see in one chart I found on the internet.
(http://www.sowter.co.uk/decibels.php)

My manual is calling out numbers like.
10 dbu at antenna jack for S1 on S meter
80 dbu at antenna jack for S9 +40

Inject a signal of 30 - 50 dbu into the antenna jack to peak 2 coils for maximum RF Voltage for the Noise Blanker.

What am I doing wrong here, I expect these settings to be in microvolts, not 10's of volts.

I have just found an article by a ham which says that 0dbuV = 1 uV into a 50 ohm load, this makes more sense to me than anything else I've read in the last 3 days.

Can someone please help me understand this.

Thanks
Kevin VE3RRH.

Kevin,
Terry (K9tw) has work these levels out and has graciously provided the level conversions on his website http://www.k9tw.com/how-to-guides and can be see here at this link on that same page "How to Convert KW dBu to Uv and dBm <https://drive.google.com/file/d/0B5NBmwIA2pskQlF6aVRxbU9QSE0/edit?usp=sharing>"
My signal generator can only go down to 1mV, so I have to insert my step attenuator in-line. I have been using 1mV= -47dBm, then add attenuation to get to the signal level that they say to use.

Jan N8CBX

51389. Hybrid net update (February 22, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-02-23 04:51:05 UTC
From: Mark Gilger
Topic: 51389 Message: 51389

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by Mark,
WB0IQK. There were 29 stations checking in under good band conditions.

We had the following number of radios checking in.

4 running TS-520(x)
2 running TS-530(x)
8 running TS-820(x)
6 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-830 + Drake L-4B amplifier.

The Sunday net was run by me, WB0IQK. There were
22 stations checking in under fair band
conditions. We had the following number of radios checking in.

3 running TS-520(x)
2 running TS-530(x)
2 running TS-820(x)
2 running TS-830S
1 running TS-510
0 running TS-511
1 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-940S + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome

as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total 142, Sunday☐s total = 88
December 2014, Saturday☐s net total 92, Sunday☐s total = 86
January 2015, Saturday☐s net total 110, Sunday☐s total = 84
February 2015, Saturday☐s net total 71, Sunday☐s total = 84 (Month to date)

Net Info:

51390. TS530S DIY Outboard Amplifier Relay?

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-02-24 00:00:29 UTC
From: yahoo@...
Topic: 51390 Message: 51390

Need to interface a TS830S to a Collins 30L-1 amp. Have the correlt plug and cable, but do not wish to ruin the delicate RF relay in the radio. Anyone have a DIY simple low to high voltage relay (kit?) that I can build? Thanks ever so much in advance. --Tom

51391. TS-830s receive quit.

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-02-24 02:42:15 UTC
From: george
Topic: 51391 Message: 51391

I am trouble shooting what was 2 days ago my working ts-830, I was listening, heard a crack, a little smoke, the receive died and the display went out. I quickly found a blown screen resistor
on the 210A line, replacing it the display came back on but no audio, and no sign of rf signal either, ie no calibrator s-meter deflection no s-meter deflection on any band.
All voltages are present on the rf and if boards, the vco frequency and levels are correct, the vfo is working. I can get 60 hz hum by touching some of the connectors or get a pop when
I change modes. I suspect a problem on the if board.

I cannot get any output by injecting a 8830 or 455 khz signal.

I looked for and cleaned up some suspicious solder joints on the if board, I double checked the connectors were in the right slots.

Anyone see this failure before.

Any help appreciated.

Thanks

George

51392. Re: [TS-520_820_530_830] TS-830s receive quit.

From: Wes Will
Topic: 51391 Message: 51392

> I cannot get any output by injecting a 8830 or 455 khz signal.

WHERE did you inject these signals? Only at the antenna input or the IF board interconnect point? Or at other points in the circuit? If you start at the antenna input and work TOWARD the IF board (or with the IF freq at the IF board and TOWARD the AF section) at some point you should get noise out of the speaker. One step back from there is where the problem is.

Please, Terry or Mike or Some-Guru, the most appropriate points and frequencies, are they listed somewhere? Or can I get some input from y'all and perhaps make a flow-chart or step-by-step instruction sheet for this?

I could likely fudge up something as a starting point but someone would HAVE to check it, preferably a couple or six someones. (I don't want to get nailed for disseminating false doctrine. I hear they burn you at the stake for that on this list, as a heretic.)

I've been laid up for a while now, and can't get to the basement to mess with my own radio; certainly can't get into the trees and onto the roof to re-build the antenna. (We're iced in and in the deep-freeze again, sub-zero C, single-digit F temps for the second solid week running. My wife - she's a school teacher - got all of last week OFF unexpectedly, there was no moving around in that entire county because of the weather.)

I need something to do, and this would help a lot of folks. (ME included.)

It doesn't take much to build a simple amplifier relay interface. You can build one using a N.O. 12VDC SPST relay found on eBay, Mouser, Allelectronics dot com, and other sources.

The N.O. (Normal Open) relay terminals are connected to the 30L1 relay contacts and the relay coil is connected in series with the TS-830 relay control terminal and a simple 12VDC source. You can use two 6VDC lantern batteries found at Walmart in series for 12VDC source which would last quite a while.

When the transmitter activates the relay the N.O. relay contacts close causing the 30L1 amplifier relay to energize and switch from standby to transmit.

Since you asked for information on building an interface I can give you a schematic so you can do just that. Drop me an e-mail off group and I'll send you a schematic.

but, if you would rather buy a ready made interface then simply follow the link provide by the previous responder..

Wayne,
The switches and "paddles" are usually supplied as two different parts. Very unusual for the switch(s) to go really bad, unless hit by something or rig dropped. The "paddles" have two fingers that slide into pockets on the switch itself. Usually...when a switch/paddle feels or is loose..one of the fingers is broken off.

Okay Tom, I'll draw one for you. I'll try to post the schematic here as an attachment. If, however, that fails then I'll upload it to my website and you can simply download it from there. I'll let you know here one way or the other.

I believe I have a 12VDC DPDT relay that would work, you simply use only the section needed to do the job. I'll check and see if I have a relay. Remember, the 30L1 amplifier has approximately 120VDC relay voltage so the relay would have to be capable of switching that voltage at approximately 100ma.

You can determine the 30L1 relay current using a DVM/DMM with the probes set to measure current. Once the DVM/DMM is set properly to measure current, connect the DVM/DMM's Black lead to the 30L1 chassis
and the RED lead to the ANT RELAY terminal. Power up the 30L1, no RF drive, and place the STBY/OPR switch to OPR, the 30L1 relay should energize and the current should be displayed on the DVmDMM meter. Set the STBY/OPR switch to STBY and remove the DVM/DMM leads. that's all there is to measuring the relay current. This same method can be used on other amplifiers as well. I have used it quite often to determine the relay current when the relay is energized. Just be careful, the relay voltage is 120VDC.

Although it will certainly be cheaper to build your own Soft Key circuit for the 30L-1 using Mike's schematic, there is also commercially-available PC board with relay from Young Kim K6HM. I happened across this on eHam today. He also offers a new PS board for the 30L-1. The Soft Key board reduces the keying voltage required, and thus reduces the wear and tear on the Kenwood's relay contacts. I would presume this is similar to Harbach's Soft Key circuit and board that's commonly applied to the Heathkit SB-200 and SB-220.

Just a little word of caution. I recently replaced all of the paddle switches in my 820S - the SEND switch was floppy loose and a couple of the others were loose or crooked. As someone once said, your rig is only as good as the last person who worked on it, and apparently, someone had GLUED some of the old switches in, so it was a real bear getting some of the old paddles out – before I realized what had been done, I actually pulled one of them completely out of the rig (switch & paddle) and had to re-attach the wires to that one and re-install it. Once I got the excess glue cleaned off the switches with a craft knife, the new switches I ordered from eBay snapped into place beautifully.

Hi Folks

I am in the process of recapping my original 41 year old TS-520 .
I need to know what a broken VR pot does.
Facing the front of the radio, It is located on the left top side of the radio,
by the left side of the CW filter about in the middle of the filter layout pattern.
I found the adjustment finger out of the pot laying on the CW filter board layout pattern.

I have no idea what it is used for, any help would be appreciated.
The radio is working fine.

Jim,
Get a bright light and possible magnifier...look around the area in question...it should be labled. From what I can gather from the 520 Service Manual there are only two VR's listed in the parts listing:
  VR1(10K trimmer pot) & VR2(500K trimmer pot)

   VR1 is for setting the "S" meter zero state
   VR2 is for setting meter for "S9" reading while injecting a   40db signal usually at antenna input and VFO set at 14.175MHz

  Hi Folks

I am in the process of recapping my original 41 year old TS-520 .
I need to know what a broken VR pot does.
Facing the front of the radio, It is located on the left top side of the radio,
by the left side of the CW filter about in the middle of the filter layout pattern.
I found the adjustment finger out of the pot laying on the CW filter board layout pattern.

I have no idea what it is used for, any help would be appreciated.
The radio is working fine.

That would be the IF board, and VR-1 and VR-2 are the choices here. There are only two potentiometers (or "pots" - "variable resistors" hence the "VR" designation) on the IF board. Which of the two is it, VR-1 or VR-2? The numbers should be silk-screened on the board itself, look at them and see which is damaged.

The User Manual for the 520 is available for download, as well as the schematic. If you don't already have them, and the Service Manual, you should get copies for yourself. They're free for the getting, several people on this list (Bob, Mike, to name two) host them on their web sites.

As for what VR-1 and VR-2 -do-? Per the Service Manual (and the schematic if you chase the circuit down), VR-1 is the S-meter Zero Adjustment, and VR-2 is the S-meter Sensitivity Adjustment. Nifty circuit. Apply the meter protection mods (See Terry's web page, several references to this in the group archive, good luck with the Yahooligan interface and actually finding it in there). Well worth the time and effort to install it.

Thank You for the help. However I do know where the other meter pots are.
This one is mounted on a small 4 lug terminal.
There is no ID on the board it is mounted exactly next to the left front corner of the cw layout pad.
I have no idea what it is for. Of course the wires go off in the wire loom!!!.
I see no pictures of it in any pictures I have. It looks to be part of the original construction.
A small tab on the metal adjustment tang is broke letting it fall out of the hole.

Thanks Jim

I need to get this straight. This 4-lug board is mounted directly ON the IF board, next to the space for the optional CW crystal filter? -HOW- is it mounted, with a bolt and nut through the IF board, perhaps the crystal filter mounting hole?

Anyone here know what this might be? I just looked at my 520SE, and not only is there no 4-lug terminal strip in there anywhere NEAR the CW crystal area, I can't see any space large enough in which to MOUNT such a thing. I know there were differences in the 520 and the 520SE, but mainly in the DC-DC power section according to what I have learned. But the differences shouldn't extend to the IF board area, I shouldn't think.

I have also gone through every picture of a 520 I can find on the web which might show that area of the innards, and again, cannot find any trace of such a terminal strip, nor again, any space in which to PUT one. Things are packed in pretty TIGHTLY around there....

Is this perhaps an early serial number with some kind of intermediate 'fix' for a design problem? Or maybe it is a very neatly done modification? I can't help much at this point, sorry. Mike, Joe, Ken, Terry, Somebody who has one of this model, or has seen the insides of them enough to know what this might be?

Otherwise, we're down to tracing the wires to their other ends, and figuring out what the thing does. Reverse engineering at its finest.

Jim,
It's been awhile since I've had a 520 series, but I do NOT think that this is a factory job. I take it that this rig is new to you? Is there anyway you can talk to the previous owner...or was it bought from someone who would not know? See if you can take several good hi-def pictures, and up-load it to the groups home page. You can up-load to "pictures" and give it a title. A msg will be sent out to group members that a new file/photo has been up-loaded, and then we can go see it.

Hello all

I have owned this radio brand new for 41 years SN 140397

I will take some pictures tomorrow and will check out the TBL bias mod
that was mentioned.

I must have broke it while turning it over. Anyway it is a 5 K pot and will be easy to replace.
I just have no idea what it does.

I found this information so maybe we have an answer as to what it is.

I discussed that as well previously in the message thread I cited.

You can also replace the terminal strip and components with a fixed resistor (approx 3.3k ohm from TBL to RLT wire wrap posts on the RF board).

Around 2.0 vdc at Gate 2 of Q2 in Send is OK.

Can also monitor TIF RF signal level and adjust the trim pot or fixed resistance until you have approx 35mv rms drive level at 14.2mhz. This assumes someone hasnt messed with the BPF transformers.

You wont find any direction in Service Manual to adjust.

From: kc0ozc@...
Topic: 51427 Message: 51427

ts-820 purchased used. had a noise in receiver audio. recapped unit and also found choke L15-0002-15 for the rectifier circuit melted. replaced choke. started alignment procedure. first step is adjusting VR4 for 9 volts at pin 2 of AF-AVR board. adjusting VR4 only results in voltage between 7.3 and 7.8 volts. I do have 14.5 volts at pin 3 of AF-AVR board (supply voltage to VR4 circuit). it appears pin 1 and 2 of AF-AVR board are both 9 volts. if i lift pin 1 i have 13 volts at pin 2. if i lift pin 2 i have 7.5 volts at pin 1 (yes pins 1 and 2 should read the same value at the same time). it seems that something is loading the circuit down after the AF-AVR board. the schematic shows pin one and two tie together immediately after the board and does not trace the individual wires, so not sure where pin 1 wire goes to. anyone have any similar experience or helpful suggestion i would appreciate the assistance.

thank you,
scott

51428. TS-520 Stiff Drive and main tuning VFO controls

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-02-26 18:54:03 UTC
From: larry@...
Topic: 51428 Message: 51428

I have searched the conversations and know the Drive control is typically a "little" stiffer. Since I have two TS-520s I have been having fun swapping between them and comparing differences. The "clean with history" 520 has a very smooth and easy turning Drive and main tuning VFO control. The "parts rig" 520, which came with no top cover and lost of what looked like red dust inside along with dust bunnies has a very stiff "as in you really need to grab it" Drive control to turn it. I have taken a brush and cleaned most of interior superficially, but I am thinking it really should have some deep cleaning, whatever that entails.

What are the recommendations for cleaning and lubing the Drive control. I already know just one drop on the variable caps, but I am not sure how to clean the ball bearings. Do I use DeOxit or some spray solvent or is spray solvent not recommended. I could use something like Acetone or alcohol with a brush, but really would like to hear what the experts use and recommend.

The VFO main tuning is a little stiffer than on the clean rig. I might not have noticed except for swapping between the two rigs. Next up I should take that apart and clean and lube it so both operate quite smoothly?

The clean rig has a noisy and intermittent audio volume control, which I assume a quick spray of DeOxit should cure with some operation of the control after the spray.

I am not in such a rush to starting doing possible damage in the repairing and restoring process.

Many thanks and 73,

Larry

51429. final unit cathode-screen grid protection mod

Topic: 51407 Message: 51430

I surrender! It is not a mod.

If you have the correct rev of the TS520 schematic it is clearly depicted.

A dual gate mosfet can be thought of in simplistic terms as a Tetrode. It needs fixed dc bias voltage applied to Gate 1 to set the Q-point on the load line. It needs dc bias voltage on Gate 2 to turn it on and produce desired signal gain at the Drain (similar to Screen grid voltage but we normally dont refer to it as bias voltage).

In this case we have approx -3.6 vdc at Gate 2 in RX mode to turn off Q2 hard so dont have your own TIF signal interfering. In TX mode we overcome that -3.6vdc cutoff bias and establish approx +1.8vdc at Gate 2 fed from RLT with the rig keyed. That 12vdc RLT voltage is supplied via the resistors and trimmer network mounted on this phenolic terminal strip on the IF board. It overcomes the offset that the minus dc cutoff bias is providing (fed via -6vdc supply from AVR board to the RF board).

Typically to turn on a dual gate mosfet and get decent gain you need from approx +1vdc to +4vdc applied to Gate 2. Anything much above that and you are in the knee of the curve. That should explain to you why we set RF-1 where we do.

Very easy to set the trimmer on the terminal strip either by measuring the voltage at Gate 2 of Q2 with rig keyed or measuring the TIF level and adjusting the trimmer for the RF voltage drive level you see listed on the TX Level Diagram. The later is easier than getting on Gate 2 of Q2.

My personal TS-520 donated by Jimmy Lamanteer had a broken trimmer so I just installed a fixed resistor from RLT to TBL and then verified that the TIF rf drive level was to spec. It would be like that Jimmy to give me a broken radio!

I have only seen 3 or 4 of these and did not make note of what serial number radios had them.

I bought a 530S at a hamfest in 2012 and used it extensively that spring and summer without any problem. I got away from using it and ham radio late that year. It's pretty much been sitting since then. I have tried it a few times over the past week and the radio does not appear to be working like I remember it.

First there is no deflection on the S-meter on any received signals I recall it moving whenever a signal was received and that was how the 5x9 readings were measured.

Second (maybe first) the signals just seem week and there is a lot of noise no matter where I tune on any band. I'm not saying I don't receive at all, it's just that there is more noise (static) than I ever remember when I used it before. I can rarely pick up anything but anyone I do pick up (even if it is loud) does not move the S-meter.

I read some old posts and they said to use Deoxit contact cleaner; but I am new to this and not sure what I am spraying/cleaning. Any help is appreciated!

> I read some old posts and they said to use Deoxit contact cleaner; but I
> am new to this and not sure what I am spraying/cleaning.

You are cleaning the BAND switch, all the wafer contacts it has on ALL of the wafers inside there.

FIRST you are unplugging it, and discharging the high voltage, see dozens of messages in the archives about how not to zap yourself inside one of these rigs. One search term might be "Chicken Stick." If you don't have one, make one, they cost about NOTHING so there isn't a price issue here.

NEXT you need some DeOxit, D-5 works pretty well. Similar brands are available, use whichever one you prefer. You will need a TINY brush or a toothpick to apply the stuff. RESIST the urge to just spray the heck out of the thing. Not only is it wasteful as all heck (and DeOxit ain't cheap), it doesn't work half as well as doing it a drop and a contact and a wafer at a time.

Put a small drop on each of the traces on the wafer, start from the front and work backwards, you can't miss any that way. After applying a small drop to the contacts, work the switch through the full range, 160 through 10-high, and back, a couple of times.

Then use a can of compressed air (or an small, reduced-pressure air nozzle hooked to a compressor if your set-up runs to that sort of thing) to remove the DeOxit and anything it knocked loose.

DON'T shake the can of compressed air. DON'T tip it and get the liquid instead of the gas flowing out.

DO have good ventilation before using EITHER DeOxit or canned air. NEITHER are good for you. As in "dead" from asphyxiation if you don't make provisions for good air flow.

DO NOT APPLY POWER WHILE THERE IS ANY OF THE DeOxit SOLUTION OR ITS FUMES IN THE RADIO. The small spark from a switch could catch it on fire, and suddenly instead of a dirty contact you're buying a new house.

Keep working the cleaner in, rotating the switch, blowing out the gunk, until you have worked your way through all the wafers on the Band switch. The whole thing will work better, even if it seemed OK to begin with, when this thing isn't gummed up or corroded/oxidized.

All of this, with pictures and more elaborate directions is available on Ken / K4EAA 's web site:

Bob

Can you turn the calibration on and see what the meter is. Try this on every band and report back. You should see ant A 9 for a properly aligned radio. We can do this starting at the basics and then delve into more technical areas as we progress. You didn't mention if you left the radio connected to mains power or antenna when you weren't using radio

I bought a 530S at a hamfest in 2012 and used it extensively that spring and summer without any problem. I got away from using it and ham radio late that year. It's pretty much been sitting since then. I have tried it a few times over the past week and the radio does not appear to be working like I remember it.

First there is no deflection on the S-meter on any received signals I recall it moving whenever a signal was received and that was how the 5x9 readings were measured.

Second (maybe first) the signals just seem week and there is a lot of noise no matter where I tune on any band. I'm not saying I don't receive at all, it's just that there is more noise (static) than I ever remember when I used it before. I can rarely pick up anything but anyone I do pick up (even if it is loud) does not move the S-meter.

I read some old posts and they said to use Deoxit contact cleaner; but I am new to this and not sure what I am spraying/cleaning. Any help is appreciated!

Hey guys, Sorry I took a while to get back to this post, and I see it generated a lot of discussion,
Mike I respect your decision and I am not at all trying to resurrect the topic, I just want to thank everyone for posting all your responses. I am in the process of reading all of them through and then will build a probe. Looking at the Clifton lab post from Terry with the ARRL probe design I think that is looking better then the probe plan I first posted, and I will go with some variation of that.
I have a bunch of NOS diodes on hand, but I am not sure if any are the right kind, still seeing what I have. If I don't have the right one I will order the parts to build a probe.
I just finished completely recapping my TS-520 and having just finished up with the high voltage cage I put in the NOS GE 6146B's and they are just waiting for me to make the probe and fire them up and neutralize them.
This will be new to me and If I have any questions I will post a separate topic on naturalizing the finals when the time comes. Yes, I have the insulated trimmer adjuster that Ken sells for this .
I already got bit by one of the 160v caps with the power off in the process of recapping and testing, I don't want to experience anything more than that.
Thanks again everyone,
73, Tom Bewick, K2BEW

Hey Rob, welcome to the group! I've been doing PSK, JT65 & JT9 with a 520S running the audio in/out of the phone patch connections and using VOX to key it. Stability hasn't been an issue after a few minutes of warm up time after initial power up! I've been running this setup for about a year now and haven't had anyone say anything about drift or issues with my signal.

Bob,
If you isolate your issue to the RF board (band switch wafers), I recommend contacting Dick Housden W0NTA for repairs. I did this on my 830S and am very happy with the results. My 830S was in storage for 2 1/2 decades which resulted in three dead bands. Apparently, these rigs perform best when used.

Dick had me remove the RF board and send it to him. No need to ship the radio. His website has the removal/installation procedure. I'm far from being a tech so this was an excellent solution. Sounds like you are in a similar place.

Good Luck.

Tom, KE0ABA

I finished building my home brew RF probe this morning.

The probe has a .0015ufd 1KV DC blocking cap, a 4.7Meg series resistor and 3 1N34A germanium diodes wires so the VTVM must be set to measure "negative" DC voltages. All components are mounted to a small PC board I designed using ExpressPCB CAD software. Perf board will work just as well and is cheaper but you will have to cut it fit the size of the probe's body.

The cable is a 3 foot length of RG-8x coax with one end soldered to the board and the other end is a 1/4" mono plug. The copper color seen in the pictures is copper conductive tape wrapped around the body. The tape and ground lead are soldered together in a small eyelet that's held to the body by a small screw. The ground is also connected to the probe's coax shield ground.

I checked/compared the probe using my Heathkit IG-102 signal generator's RF and AF outputs. The homebrew RF probe produced the exact same AF/RF test results as the Heathkit PK3 and 309C RF probes did. The probe has 3 1N34A germanium diodes so the maximum RF level it can measure is approximately 90 volts or less and the maximum DC voltage the probe can be subjected to is approximately 1KVDC or less.

I uploaded 3 pictures of the probe on my website (website is currently being modified/updated). The website's current pages and links work fine. Except for the time it took to have ExpressPCB make the small PC board, it took about an hour to build. I plan on building another one, exactly the same but without the copper conductive tape, to see if the tape is actually needed.

The mistakenly said the "tape" was soldered and that's not true. The connection to the tape is through a screw and eyelet where the ground lead and PC ground are connected. The PC ground and ground lead are soldered to the eyelet that is then held against the conductive tape with a small screw.

I uploaded a simple amplifier interface drawing on my website. It's in the Manuals and Documents page.

The 12VDC battery shown in the schematic are two 6 volt lantern batteries, found at Walmart, that are wired in series producing 12 VDC. The polarity, positive or negative connection to the TS-530 Remote socket, pins 2 and 4, does not matter since pins 2 and 4 are a simple N.O. (Normally Open) set of relay contacts that act as a simple switch.

The relay terminal connections to the relay amplifier socket do not have polarity issues, the relay terminals are a simple switch. You will need the appropriate DIN and RCA plugs for the TS-530 REMOTE socket and the amplifier's relay socket.

Bob,

These radios do have several common and reoccurring problems. I wouldn't too quick to pull boards without first going through the basic steps. Once you have turn the cal switch on this will give an indication, a properly aligned radio should show about s9 on the meter with the cal button turned on all bands, 10m maybe slightly down, the cal switch is used as a basic tool, especially when no other signal generator is available. I would then look at the relay, unfortunately, this far too often gives problems. As these relays aren't sealed units, the contacts are subject to corrosion, this then causes high resistance, they can be burnished, this will provide limited success, best to replace. These relays are no longer available, Ken, has developed a daughter board that will give many years of good service. It is easy enough to replace as long as patience is employed when removing the molex connectors and not over heating the tracks when removing and soldering the new relay board. I would try the tap test on the relay first to see if this makes any difference, sometimes this works sometimes it doesnt.

Whilst going straight at the RF board vertical wafers with Deoxit, you want to get to the root cause of the problem, when repairing or undertaking repairs to these radios you must be methodical, start with the most common issue and then work up to the more complex, especially if you are not familiar with repairing. It is a great learning curve and will teach so much more than just sending radio out for repair or not being able to do basic repair\trouble shooting. This forum has some of the greatest radio repair\technical people and the great thing is they are really interested in these hybird radios and also teaching people.

My two cents worth.

OK, before I have done any cleaning or chicken stick building, I turned the radio on, and pressed the CAL button in. There is no movement on the meter. I go through the same thing for each band with the same results on each except for maybe the slightest deflection on the 10m band. It jumps just a little bit there and then back to 0 - zero.

What's my next step?
Cheers

Ok a bit more information.

I did a few "taps" on the Omron relay and tried the CAL switch again. I don't know if the tapping had anything to do with these results or if the radio just needed to be warmed up more however:

160m - meter reads 0
80m - reads 5.2 on S scale
40m - 7.5
30m - 5
20m - 3.4
17m - 4.1
15m - 7
12m - 7
10m - 3
10m(high) - 6

(I'm sending this again, I posted once but it didn't show up..sorry if it appears twice)

Ok I did a bit more testing and tapped the top Omron relay before trying the CAL button again. I don't know if this did anything or I just needed to let the radio warm up:

Results:
160m - meter reads 0 on "S" scale
80m - 5
40m- 7.2
30m - 4.8
20m - 3
17m - 3.5
15m - 7
12m - 7
10m (low) - 2.8
10m (high) - 5.5

Had off forum questions about converting a TS-520X to a TS-520 (100 watts output).

Dont want to waste the bandwidth on such a parochial subject or incur anyones wrath so will limit comments here. I have only seen two 520X rigs and it has been quite some time ago. Differences that I recall include:
1. Uses a single S2001A final tube. Point to point wiring on octal socket.
2. Uses the 400 tap on the transformer secondary instead of the 800 tap.
3. Uses a full wave bridge rectifier with only one of the two HV filter caps installed. This is in lieu of the voltage doubler. Anode voltage will be approx 400 vdc no load and approx 375vdc key down.
4. Screen grid voltage is reduce to approx 160vdc with a series dropping resistor.
5. RF drive from the 12BY7A is reduced by a 10 to 15 pf shunt capacitor at the S2001A final control grids.This means approx 35rms rf volts drive in lieu of 45rms rf volts.

This is what I remember and it may not be 100% accurate. Unfortunately I did not take the quality of notes or photos that I should have. The reason I post this here is to get it corrected if my recollection is wrong.

Additionally, I would like some HELP from members who own a TS520X or V (V has a final board).
1. What is the anode voltage displayed on panel meter in HV position both in Rx and Tx mode?
2. At max RF output what is the plate current Ip level? (My guess is around 100 ma).
3. What is maximum RF output in CW mode?

I have prepared a white paper on the differences between a TS520 and a TS520X and how to convert the TS520X model to 100 watts output. I will be posting it on my website http://www.k9tw.com http://www.k9tw.com in the next day or two depending on any needed revisions based on feedback that I get.

By the way just got a new Bird 43P wattmeter and elements after 50 plus years in the hobby! I have to say that the ballistic characteristics are quite different from my trusty old Drake W4s. No way to justify it, but thanks to the many customers who have entrusted their treasures to me. I will continue to upgrade my bench so I can provide better service.

Please respond to my questions off list. I will not address any additional discussion about the TS520X model here.

For sale a Kenwood R599A receiver (silver front panel) with both 6 and 2 meter converters installed (they were installed when I bought the receiver back in 2010).

I have the R599 operator's manual plus the 6 and 2 meter convert manuals in pdf format (will be copied to a CD).

Receiver works very well but the VFO is susceptible to warble when the case is tapped. I have not used the 6 and 2 meter converters. The case has no dents, no extra holes drilled, has original paint and hold down snaps on the top cover and the front panel is in excellent condition and all controls work properly. All knobs are original and both meter and dial lamps work. I have one hard to find 16 pin plug with cover for the rear panel control socket that is included with the receiver (I will not sell the plug separate).

Price is $150 plus actual packing and shipping cost. I do not pack items I ship, I have the local UPS/FEDEX agent do the packing.

If interested contact me off group at */my call at yahoo dot com/*.

Hi again Folks

Thank you all for the help.

I installed the a 10 K pot as it was what I had to replace the 5K VR11.

I adjusted the voltage to -3.86 RX and 1.87 TX and all is well.

I measured the ohms and just like Terry said 3.3 K is the sweet spot.
I bought the Kenwood TS-520 in early 1974 but by the serial number
I see the the year of manufacture was 1972 according to the information I found.

Thanks to all and to Terry K9WT the master.

To say that it is "undocumented" is not correct.

I am looking at it on schematic as I type this. You just need the correct rev of the main TS520(M) schematic. It is depicted just to the left of the RF board.

Jim,

Is there some scheme to figuring out the manufacture year and where in the entire run of serial numbers my TS-520 fits?

Does anyone know the start and stop years of manufacture of the TS-520?

The S/N is: 460218 and I think I purchased it in 1976 from Harrison Radio (SK) on Long Island.

As I recall it has one of these unspecified trim pots also. I remember poking around the IF board when I did an alignment and not being able to identify a pot which looked to be rather "tacked on" compared to the rest of the construction.

Jim,

The only reference I know for serial number vs. mfg date for Kenwood Hybrids is at the WB4HFN site at the link below.

You may be able to triangulate with this information.

Jim,

Is there some scheme to figuring out the manufacture year and where in the entire run of serial numbers my TS-520 fits?

Does anyone know the start and stop years of manufacture of the TS-520?

The S/N is: 460218 and I think I purchased it in 1976 from Harrison Radio (SK) on Long Island.

As I recall it has one of these unspecified trim pots also. I remember poking around the IF board when I did an alignment and not being able to identify a pot which looked to be rather "tacked on" compared to the rest of the construction.

51460. Hybrid Net Update (March 1, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-03-01 19:52:16 UTC
From: Mark Gilger
Topic: 51460 Message: 51460

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by Mark,
WB0IQK. There were 31 stations checking in under good band conditions.

We had the following number of radios checking in.

6 running TS-520(x)
3 running TS-530(x)
4 running TS-820(x)
3 running TS-830S
0 running TS-510
0 running TS-511
1 running 599 twins
0 running TS-900

I was running my TS-830 + Drake L-4B amplifier.

The Sunday net was run by me, WB0IQK. There were
14 stations checking in under fair band
conditions. We had the following number of radios checking in.

2 running TS-520(x)
0 running TS-530(x)
3 running TS-820(x)
3 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-940S + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome

as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total 142, Sunday☐s total = 88
December 2014, Saturday☐s net total 92, Sunday☐s total = 86
January 2015, Saturday☐s net total 110, Sunday☐s total = 84
February 2015, Saturday☐s net total 103, Sunday☐s total = 98 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

It is also shown on the TS520(K) schematic that I have here.

Not always easy to decipher the Edition or Rev numbers on the bottom right corner of the rear covers of the Operating and Service manuals.

Even knowing the date wont tell you what is different in the manual. I know of no errata sheets or revision or update summaries in any of the documentation. Over the years I have tried to annotate schematics and manuals as I discover differences in the actual as built configuration.

Hi Garry

Check this out.
http://www.wb4hfn.com/KENWOOD/Presentations/KENWOOD_FORUM_2014.pdf
http://www.wb4hfn.com/KENWOOD/Presentations/KENWOOD_FORUM_2014.pdf

I found a site that said take the serial number of the older units like mine.

140397 change to X4XXXX subtract 2 from the second number in my case 4
which will give you a 2 so 1972 is mine. Look at the dates of some of the parts
in the radio and that should get you close. That is what I went by.
I believe the first units were sold starting in the fall of 1973.

Concerning the mods, I looked a bit closer at the mods on the PDF and it is easy enough to see how these go on the 520. The curcuit board on the bottom of the tubes on the 830 through me off a bit, but I see the diodes and Varistors go to ground from pins 1 and 3, the cathode and grid, which look to be the same pin numbers on the 520 too. And the the 2 W resistors on the HV are the same. Sorry for not looking a little closer before I wrote, looks easy enough.

Apparently this serial number decoding doesn't work the the TS-830S. My serial number is 3100074. If I subtract 2 from the second digit it leaves a 9 for 1979? Kenwood didn't start selling the 830S until September 1980, according to WB4HFN.

All that said, I bought the radio in 1983. So, if I ADD 2 to the second digit, it gets pretty close. Doesn't really matter, just sayin'...

What does any of this have to do with an "Unknown VR pot"?

It would be more helpful to make a serial number
subject rather than hijacking an unrelated thread.

Hello everybody,

I am in the proccess of connecting the TS-820 and R-820 together, but I have some doubts even reading through the manual of the R-820 where it says about the possible options. The TS-820 has to be modified depending on what option is chosen. I suppose some of you having these two beautiful rigs have gone through the same situation and doubts. What mod should be done on the TS-820 according to the R-820 manual in order to allow me to use the TS-820 with or without the R-820 if I anytime want to use it on its own?. In case of using it with the R-820, will the external VFO-820 be operational??. Sorry but I am quite confused at the moment and I hope any of you can help me with this.

Best regards to the Group and many thanks.

Carlos, EA1XF

Hi Tom,

Don't take it personal, you were just the last in the list and I replied to it. I urge you to keep contributing but it sure helps if the topic reflects the discussion.

Not everyone received their information from this group in the same way, some guys even get daily digests in email form. Turn the situation around and consider the poor guy on dial-up that gets a daily email digest. Let's say he was looking for the very info that you posted but skipped it because the subject matter didn't make sense to him. It goes both ways.

I venture that the only evil that will befall you in this group is that someone might miss out on what you or someone else has to say or a moderator might have something to say about it. This was brought up not much more than two weeks ago - see MSG #51302 on Feb 14

Topic: 51469 Message: 51472

Carlos,
If you want to keep it simple, just route Pin 4 on the R-820 rto the TS-820 remote VFO pin #5. All that will do is mute the R-820 when you are transmitting on the TS-820. You can then use the R-820 to monitor any freq. on the same band or different band than what the TS-820 is set up for. No TS-820 modifications are needed. I did that for several years when I had my TS-820/R-820, because I did not have the correct cable to interface both of them. After doing it the simple way, I never thought about obtaining the cable as it seemed to be so much more useful this way.

Mark, WB0IQK

Hello Mark,

Many thanks for your reply and help. One of the amazing things about this hobby is how we experiment. In this case, you managed to find out that way to make it work even without having the original cable; congratulations. You know, it cost me a big effort and long time to get the original cable, which I haven´t tried yet, so I still don´t know how the will work together connected directly. I have always said that manuals sometimes can only be understood by the person who wrote them. In this case, some details are not very clear and the translation into English is a bit confused. If you add to this that I am not a native English speaking guy, it even makes the situation a bit more confused, hi, hi. That´s why I thought posting my message to the Group and I am sure we will hear more comments and experiences about this and how to do it and its consequences.

Thank you again and 73.

It does indirectly have to do with the VR pot since serial numbers were mentioned.
Interestingly I also have a VR Pot on my TS-520 and it has a low serial number (I don't have it in front of me now) but I think it is around 13xxxx.
However Tom, the serial number convention you are thinking of is a newer one that does not at all pertain to these early hybrids. Kenwood did not use any such formula back then. Other then the fact that the lower the number the earlier is the radio. Unfortunally Kenwood has no records on those numbers. I contacted them directly a few months back and they let me know they have no reocords and could not help me. There is a serial number data base that has been started by a forum member on his website for people with Hybrids that have known purchase dates so others can place theirs in the ball park of the year. So, If you have one and you know when you bought it new you should get it added to the list to help others by contacting the fellow who owns the website.
That list is located at the following website and is a PDF file under the link "Kenwood Serial Number Database"

http://www.wb4hfn.com/KENWOOD/Kenwood-Articles.htm

51475. The live chassis 520s up-date

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-03-03 10:44:51 UTC
From: beeson.neil@...
Topic: 51475 Message: 51475

Been into the TS 520s and found the HV Caps were blown, shorting straight to ground, solving the live case problem. Cracked solder joints around the 12by7a and original S2001A tubes so now she tunes up sweet as a nut (with the S2001A's) after coming back to life after 10 hours on the variac, had a 4' piece of coax out back and heard 2 stations in Indonesia talking. One problem driving me nuts is the audio from it, one minute there's not a sound coming out but give the chassis a little tap on the left side with the cases off and speaker comes to life. Something is loose, I've cleaned h/phone jack connectors and rear speaker jack, tried another speaker checked everything, still the same. After the speaker comes to life it's fine until the next time I turn it on, I've got to tap the left side chassis again so I'm missing something. Any help will be a great help, I'm just happy to bring her back from the dead. Cases will be painted next weekend now I know it WORKS
73
Neil
VK6NSB

PS
Radios not turned on for some time BRING THEM UP ON A VARIAC FIRST!!!
I reckon that's what blew the HV Caps, straight to 240v AC

51476. Re: [TS-520_820_530_830] The live chassis 520s up-date

Topic: 51475 Message: 51476

Hi Neil,

Try tapping on relay RL1 located on the top left rear of the chassis.
RL1 can be seen by looking on the right and below of the VOX Unit board.
Using a insulated tool and tap on RL1 when the problem occurs again. RL1
has a wire clamp that hold RL1 down onto it's socket. Quite often this
wire clamp may be missing allowing RL1 to move about in its socket. RL1
performs a number of task when switching from receive to transmit and
vice verse.

  What does any of this have to do with an "Unknown VRpot"?

It would be more helpful to make a serial number subject rather thanhijacking an unrelated thread.

From: W5RKL
Topic: 51407 Message: 51478

I don't know what email client software most members use, I use Thunderbird. Thunderbird is FREE and it allows the operator to create message filters. Message filters control how an email message is handled when it's received. For example, a message filter can be made to route all messages pertaining to the subject "TS-520" to a TS-520 folder created by the operator. A filter can also be made to route all messages that have eBay in the "From" line that pertain to eBay sales/purchases by the operator. A message filter can be create to handle all message relating to Paypal. I have a separate folder for eBay and Paypal. Any message originating from eBay or Paypal is routed to it's appropriate folder so I don't have to dig through messages just to find eBay and Paypal messages. A message filter can even be made to route messages to the trash folder and if the account option, "Empty Trash on Exit" is selected, all those message that were routed to the trash will be deleted.

If you are using an email client software package, check the options and tools available to you within the software. You might find it rather easy to eliminate all that scanning through email after email to find one you are interested in. Knowing how to program is NOT a requirement, simply look and select the options you want and enter the originator, subject, or other text that will identify the message and then select how the message should be routed. It's easy and saves a ton of time.

Outlook allows me to do that and I do, as I receive as many as a 1000 emails a day. The auto sort and file system is great. I can also create ‘rules’ to designate any number of parameters found in an email header, as spam and how to handle it. (I just tell the rule to delete the garbage.)

Ok I have question for all you restores, how do you go about cleaning the innards of the radio?

Do I need to pull all boards out and totally strip it to bare frame? My radio has some dust and film on the metal parts that has attracted dirt.

I see most boards can be wash with Palmolive soap and distilled water, probably not a smart idea to just hit the radio with a spray bottle with boards still mounted. I just want to give a freshening up and make lot nice inside.

So any ideas are welcome.

Radio is a TS-820S, it has a broken band switch coupler and a few lamps out but it works like a charm with 105 watts out. Tubes I think are the orignals Matsu 2001's

Thanks all and love this forum.

Chad, I also should have asked, are you using a microphone with only 2 wires and a shield, one wire is the microphone positive element, one wire is PTT, and the shield is the ground for both microphone element and PTT? Also, what pin are you using for microphone ground at the microphone cable plug?

51486. Need photo 530S variable capacitor frame connection cleaning

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-03-05 05:16:57 UTC
From: Wes Will
Topic: 50578 Message: 51486

Trying to help a new member, he isn't 'up' on a lot of things, and it sounds to me like perhaps he has a dirty main tuning capacitor frame connection. Symptoms include weak receive, and the cal tone varies in strength semi-randomly as you go up or down on the dial. Sometimes he says he receives CW or side-band transmissions, sometimes not, sometimes there but weak, depending on the exact freq.

It's one of L41, D2, or the frame connection inside. He asked me for pix, and frankly, I can't find a good one. Does ANYONE have a photo online somewhere of the back end of the main tuning vari-cap, showing the bronze fork that needs to be cleaned? Any -other- details, how to get to that part (what to remove, what to leave alone), precise cleaning details, or anything else, it would be appreciated. He's on this list, if you post here it will get to him right away. (And if he wants to step in and ask personally it won't hurt my feelings at all, either.)

I've already mentioned not poking/prodding/bending it, and the basic info on phosphor-bronze contacts, but a picture here would be worth me not typing several thousand words.

Thanks in advance.

G'day Mark We took the relay out and cleaned the contacts with Deoxit and found some dirt in the base plug. But the big news, searching the net put in a bit of info, in the AF UNIT is 2SD90 transistors with loose retaining nuts. And sure enough, she nows run as sweet as a 2 bob watch. So now another TS 520S saved from death and it even still has original S2001A tubes and tunes up a dream. Re-paint is the final part for this lovely Kenwood to come back to all its glory
Thanks for your help.

Wes

There are two rotor shaft wiper contacts on the 530/830 VFO air variable cap. One at the outboard end and one at the inboard end. Very easy to pull the VFO and remove the shield can to access both wipers. They are shiny nickel colored and not copper/brass colored.

Must be careful not to strip the 4 fine thread screws that secure the perimeter of the shield can. I find them cross threaded. Also there is a larger screw on the rear of the can. Need to snug it first and then install the other four as they go in slotted holes. The screw on the back comes in a variety of configurations from having flat washers inside and out and/or a star lockwasher. I sometimes find a flat washer floating around inside the shield can!

While there good idea to back off the PC board mounting screws and gently re-snug them. Also can use a point of toothpick to apply very small amount of grease like Magna Lube G or Super Lube (both are PTFE based) to the ball bearings in the race at inboard end. Also, I use artist brush to apply very light amount of Tri-Flow to entire gear train set (pinions, anti-back lash gear sets etc). Usually will stop any noise and make it run silky smooth, but of course cannot compensate for gross axial or radial play due to worn bushings. A little axial play is normal but should not have lot of radial play.

Last caution is to make sure you dont pinch the two sets of analog dial lamp lead wires when you re-insert the VFO in front panel and tighten retaining screws.

Topic: 50578 Message: 51490

I have looked but can not find any pictures in our file/photo area.
The procedure is simple:
     Obtain a good contact cleaner/lube...many use DeOxit
     Obtain some "canned air." aka "air duster" find it at office supply/computer stores...and at WalMart too.

      Obtain a 3.0mm "Allen" type tool...aka "Allen Wrench."
       Remove all power to rig...unplug it from the wall socket.
       Using the "wrench" stated above...remove the four "allen" screws on the front panel that hold the VFO in.
        SLOWLY pull VFO towards you. Be careful of the two small lamps(red wires) and the VFO connection plug on the rear of the VFO.
        You can leave the small lamps in place..IF there's enough slack...if not the can slide the lamp holder forward to remove the lamps.
       Unplug the connector from the rear of the VFO.
      Remove the 4 screws around the outside of the silver cover. Remove the screw on the rear of the VFO. Be careful...as there may be some small washers in the inside that are used as spacers. Slide the silver cover off.
   The VFO wiper that needs to be cleaned is at the REAR of the air variable capacitor (the thing that turns)
   Spray cleaner/lube on the wiper...rotate the VFO knob through its travel several times...blow off with "canned air." Repeat application of cleaner lube...but this time DON'T blow off. You can also apply 1(one) drop of a light weight, non-parafin based lube to the bearings at the front of the air variable cap.
Put silver cover back on VFO and connect the connector on the rear.
  Plug rig back in...and power it up. Test VFO for proper function...no skips...drop outs...etc...If all is well...put lamps back in and slide VFO back into chassis...be careful that the red wires for the VFO lamps don't get pinched.
DO NOT poke, prod...or otherwise mess with the VFO wiper! You'll be sorry if you do!
You can go to n6wk "dot" com and look at the TS820S VFO servicing procedure. You will see in the pictures what you need to clean. Disregard the assembly procedure. You VFO come out the front as stated above.

When I clean the VFO wipers I also clean the bearings which quite often have dirty grease. I then apply some conductive grease, DeoXit L260ap. My SB-303 receiver LMO had constant erratic tuning problems, even after throughly cleaning the flex wiper. I ended up having to remove the LMO, thoroughly clean both ends then apply DeoXit L260ap mechanical and electrical conductive grease to the bearings. That was a year ago and so far I have never had anymore erratic behavior in the LMO and the LMO still tunes very smooth.

Just my 2 cents.

Looking for a diagram (mechanics) of the VFO-assembly of the TS520S ;

main tuning dial locked up , Knob is turning but subdial is stuck.......
would like to know the best appraoch for this problem in order to avoid
any further damage to the assembly !
would vy much appreciate detailed info in order to fix this problem.

73's de Tom , PA3EZB .

Tom,
Look on PAGE 39 of the TS-520S SERVICE MANUAL. There is an "exploded view" of the VFO
A Service Manual can be found at: n6wk " dot" com and I think Mike-w5rkl may have one
also...w5rkl "dot" com

Joe is right, I have the TS-520S service manual on my website.

www.w5rkl.com

Click on Manuals and Documents link at the top of the page. Once the
page comes up, click on #7 under the Kenwood Manuals and Documents listing.

This looks great! Has anyone replaced the internals of a Kenwood VFO-230 with something like this? Mine has been well butchered before I got it and I seriously doubt it's accuracy. You would be able to eliminate a lot of the old internal stuff.

Go to Gordon N6WK site and download the TS520 owner/operator instruction manual. The main schematic (fig 38) in that manual shows it. Just left of the RF board near the RF gain pot.

From: roberteleazer@...
Topic: 51498 Message: 51498

Some of y'all may recall the discussion we had here a while back about replacing the VR2 meter sensitivity pot on a TS-520 I have been working on.

After buying a replacement pot and then doing more troubleshooting before I installed it, I decided the existing VR2 was working after all.

However I also discovered a detail left out of the schematic in the manual. VR2 is used as a variable resistor but is connected with the center wiper hooked directly to one of the other end connections. Of course, this is a common technique, but is not reflected in the schematic that discusses the IF board. Failure to know this will result in some confusing readings.

Anyway, now I have to go figure out why the meter sensitivity is acting strange.

Best regards.

51499. VFO-820 not switching frequency on TS-820

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-03-06 11:39:59 UTC
From: nesseca@...
Topic: 51499 Message: 51499

Hi,
I recently purchased a VFO-820 in what appears to be in excellent condition and noticed that when it is in the "REC" mode the digital display on my transceiver goes out and I'm not able to tune. The only time the transceiver display comes back on is on during "XMIT" (which still won't allow me to tune from the vfo) and of course, "OFF". Does anyone have any ideas what might be causing this? Hopefully it isn't operator error.

Thanks.
Craig

From: Mike W5RKL
Topic: 51499 Message: 51500

Craig,

My first suggestion is to check the interconnecting cable, there should be no cross over connections. The connection is pin to pin, meaning pin 1 on one end is connected to pin 1 on the other, pin 2 to pin 2, pin 3 to pin 3 and so on.

Pins 8 and 9 control the TS-820's internal AND remote VFO-820 power. Pin 9 provides the +9VDC from the TS-820 to power both internal and external VFOs while pin 8 is the B+ path determined by the VFO-820's FUNCTION switch position(s) and VFO-820 internal relay.

If you have a DC volt meter remove the VFO-820 cabinet and connect the DC volt meter to the "B" terminal on the VFO-820 PC board. Connect the interconnecting cable to the TS-820's remote VFO socket, power up the TS-820, and place the VFO-820's FUNCTION switch to REC. The DC volt meter should show +9VDC. If the DC volt meter display 0VDC then the problem can be one of the following:

1. Very dirty VFO-820 FUNCTION switch
2. Dirty VFO-820 relay

If you do not have the VFO-820 manual, I have a very clean clear copy on my website with a clear schematic.

www.w5rkl.com

Click on the manuals and documents link at the top and when the page comes up, click on Kenwood manuals item #13.

Robert

Apparently you are not old enough to recognize the schematic symbol for a Rheostat.

This is a standard way to show how it functions electrically. The standard symbol for a Rheostat is a resistor with an arrow drawn thru it. Sometimes they will also draw a rectangular box with an arrow thru it.

When you see that you know it is not wired or functioning as a Potentiometer. That symbol tells you the resistance varies from zero to max ohmic value. Nothing proportional. It can be a 2 terminal device or a 3 terminal device with the wiper tied to one leg.

You just dont see that symbol very much anymore. Probably more prevalent in Electrical Elementary drawings that an electrician would use and not so much in modern electronics. One exception might be antique radios that often had a Rheostat for filament voltage control and maybe even a window to view the filaments.

You would probably be happier if it was drawn the way it is on the TS530 IF Board schematic (Q7/Q8) for example? Of course, not drawn that way on the TS830s. KW didnt standardize.

Remember the schematic shows how it functions electrically and does not reflect as built physical wiring. In electrical power work the electricians must use both the Elementary and the Wiring Diagram when troubleshooting. We dont have Wiring diagrams for KW hybrids and not very common for communications gear.

Absent wiring diagram about best we can do is look at the Xray view and can then see it is a 3 terminal potentiometer wired as a Rheostat.

Teryy:

Oh, I know what rheostat is. As a matter of fact Radio Shack sells what they call a pot but is in fact a rheostat with only two terminals, one end and the wiper - I found that out the hard way, buy trying to install one in an application that required a pot for a volume control. A visit to a local surplus outfit produced an exact replacement for that 1960 vintage radio. By the way, a previous owner must have concluded the ON/OFF switch built in with the pot was bad and removed it and the associated knob but never replaced it. In reality I found that the set simply had a bad line cord.

But to me hooking a pot up as a rheostat means one end and the wiper hooked up and that's all. I know that occasionally one end is shorted to the wiper, which changes the response curve significantly, although I confess I don't know why it is done that way, other than to slightly increase the current handling capability by giving current more than one path than just through the wiper.

In any case, it threw me off when trying to figure out if the VR2 pot was good or bad. It seemed erratic, showing zero ohms at one end or the other.

I still have to figure out why the meter calibration is not working properly. I'll feed the radio a signal from the HP-606A and see what happens.

Have a good weekend!

Robert

Hi Mike,

Thanks for the reply. I've tried it with a different VFO and a different cable and it acts the exact same way; so now I'm thinking it's the transceiver, but I had it serviced recently. I do remember I had a VFO that worked before this rig had any work done on it. Are there any tests I can perform to see if it's the transceiver itself? Thanks again

Craig,

Remove the VFO-820 interconnecting cable from the rear of the TS-820
then jumper the 820's rear panel remote VFO socket pins 8 and 9 with a
short wire or the factory jumper plug. Power up the TS-820 and check for
normal transmit and receive using the internal VFO.

51506. Hybrid Net Update (March 8, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-03-09 00:12:33 UTC
From: Mark Gilger
Topic: 51506 Message: 51506

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by Mark,
WB0IQK. There were 18 stations checking in under good band conditions.

We had the following number of radios checking in.

3 running TS-520(x)
2 running TS-530(x)
4 running TS-820(x)
6 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-830 + Drake L-4B amplifier.

The Sunday net was run by me, WB0IQK. There were
12 stations checking in under fair band
conditions. We had the following number of radios checking in.

2 running TS-520(x)
1 running TS-530(x)
0 running TS-820(x)
2 running TS-830S
1 running TS-510
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-940S + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome

as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total = 142, Sunday☐s total = 88
December 2014, Saturday☐s net total = 92, Sunday☐s total = 86
January 2015, Saturday☐s net total = 110, Sunday☐s total = 84
February 2015, Saturday☐s net total = 103, Sunday☐s total = 98
March 2015, Saturday☐s net total =18, Sunday☐s total = 12 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

51507. Remove VFO better in receive???

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-03-10 15:01:35 UTC
From: n4bos@...
Topic: 51507 Message: 51507

Hi all,

Good to be part of the group.

I have had my 520S since the late 70's and it's still my favorite radio. I do have a question about it though. I have a VFO-820 that I have used with it for years. It works well but I noticed today that when receiving with the VFO-820, the signal is noticeably louder... about one S unit (3 dB) than with the internal VFO in the 520S. Wonder if anyone elswe has noticed this and if it is a common "observation" (as opposed to a problem)? This seems to be the case regardless of band. It's not something I am going to rip the radio apart chasing but more curiosity than anything else. Other than this minor "issue", The radio works well and I have had no issues with receive.

Any ideas or comments?

Thanks!

Steve

With the Kenwood hybrids, the remote VFO tends to be more frequency stable than the transceiver's VFO due to greater thermal changes within the transceiver. At least that's been my experience...

As to the higher S-meter reading using the remote VFO, I haven't seen this with any of my hybrids, but have seen it with my old Ten-Tec gear. Using the remote VFO (actually a PTO) with my Ten-Tec Omni A Series B, I actually notice a decrease in S-meter readings when switching to the remote. This is due to changes in the injection level from the remote VFO.

My friend's father died a couple of weeks ago, and I didn't know until the funeral that he was a ham radio guy. I told her I was glad to hear that - that I had my license almost a year and a half now and was really enjoying it. She asked her Mom, and they wanted me to have his equipment.

I went over and picked it up today, and they had a 520 that for some reason had some trouble, and he hadn't used it in years. It looks great, though, along with an MC-50 mic. There were some other SWR meters, an antenna rotor control, an Icom mobile FM transmitter, Astron power supply, and other neat stuff.

How sweet is that? Thank You, Lord, for that blessing! I can't wait to get time to work on the 520 to get it up and going, but if I have questions, I'll check with you guys.

Hi all -- usually a lurker, but thought I'd chime in with my opinion.

This is a symptom of a signal strength issue with your TS520's internal VFO (compared with the external VFO). The strength in dB of the output on receive (and transmit) is directly related to the signal level of the VFO as it feeds into the VFO mixer (Q2 and Q9 on the 520). If you look at the schematic, that signal either comes from the internal VFO, or from your Remote VFO.

If I were debugging the issue, I'd either say there is some issue along the VFO amplifier chain (VFO OSC, Q4, Q3, Q2) -- less than perfect contact on a solder connection, capacitor going bad, or just natural variation in all the components. You could verify this by putting an oscilloscope on the external VFO and comparing the signal strength to the internal VFO's signal level at the same point.

Ben:

You are exactly correct the first thing to look at is the VFO input signal at the VFO wire wrap terminal post on the IF board just ahead of the LPF. As you note the VFO is the LO for Q9 mixer. LO injection level needs to be approx 800mv to 900mv rms. (KW reduced that to 200mv on the TS530/830 due to PLL mixer requirements)

It would be more common for someone to have adjusted TC-2 on the internal VFO. I often find that the remote VFOs are far less molested. Could also plug and unplug the RCA plug on rear of internal VFO to wipe that connection. Can do that with needle nose pliers without moving the AVR board.

The fellow who bought the VFO made a wise investment. Having an exact matching analog VFO is more useful than just facilitating chasing DX. It is also a great troubleshooting tool when you are experiencing drift and/or frequency jumping. Can isolate if due to the internal VFO or problem on the AVR board (regulation or dirty trim pots both 9vdc and RIT) and it allows you to even out the gear train wear on the internal VFO. Very rare for the Remote VFO to exhibit excessive axial or radial play, drag, and noise. Usually many more revolutions on the internals.

I have two VFO-240s married to my TS830s and would not be without them.

If he has O-scope or RF millivolt meter he could also adjust output level on the remote VFO and watch the effect on S-meter. Just have to set TC-2 back to around 900mv when done. It can also be too high as well as too low. A topic for another day.

Lastly, if the Op has a decent RF sig gen can also run Rx Level Diagram.

Not a big deal but I would want to know why. Clearly not normal as some might think.

Terry K9TW

51515. TS830S Tuning Knob Hard/Drags?

Yahoo group: TS-520_820_530_830 (2015 — 2016)

(new to me) '830S which, when rotating the tuning knob, doesn't feel as sooth as it should be.

Replaced the knob, outside silver plastic dial, and washers/sprint, but no change.

My '530S is smooth and light, this one is noticeably a bit harder to tune.

Any ideas?

Thanks in advance!

The VFO gear train needs cleaning and fresh lubrication. Luckily, the unit is very easy to extract from the radio and it's cover is equally handy to remove. I used denatured alcohol to dissolve the old, hardened grease from the gears and shafts in my 830's stiff tuning VFO and CorrosionX (sparingly) as fresh lubricant. Others can offer alternative and possibly better suggestions for regreasing/oiling.

Your VFO will soon be as smooth as glass with a good cleaning and lube job.

Thanks Craig!

I would assume that the removal would be fairly easy?

Take off the 4 bolts from the front of the radio, disconnect the wires and pull out?

Any "gotcha's" on doing this?

I have deoxit - will that work for the lube?

Along with a great condition '830s (with sluggish VFO :), the VFO-230 is fine when first powered on.

That is, the digit display seems to creep slower and slower both up and down the frequency range.

After 10-15 minutes of "warm-up" (wow, it gets hotter that I would have though), the tuning becomes sluggish. Pulling the plug for a few minutes restores normal operation, but starts again after 10-15 minutes or so.

Is this something that's relatively easy to fix?

Would loosening and tightening the circuit board screws, unplugging and replugging in the connectors help?

Thanks in advance.

Hi Tom,

Nope -- no gotchas, other than making sure you gently pull the light bulbs free of their silicone holders before pulling out the VFO.

I'm not sure DeoxIT would work well as a lubricant, at least with any lasting power. CorrosionX has a lubricant and anti-seize agent in it. To my knowledge, DeoxIT does not.

Any decent oil or light grease used sparingly should work, however, including something like straight 20W motor oil, sewing machine oil, etc.

Good luck. I hope to hear you on the Kenwood Hybrid Net soon.

Tom,

The VFO230 has some fundamental issues. You will find that after 30+ years the electrolytics predominately on the power supply board are starting to see the end of their life. Yes these ext VFOs run warm. I had similar issues with mine with initial drift, but a little unsure of your creeping frequency issue, need more information to determine your description. If left turned off and unplugged they do have a mind of their own until completely warmed up, I have seen mine (3x units) drift up and down. Trying to use the VFO in this state is almost impossible as you loose the ability to change frequency with the encoder, store freq correctly etc

What I do is leave mine plugged into the mains, this keep power up to the memories and as the unit is warm assists with minimizing drift, as you know when you turn the radio on it brings the VFO to life aswell. Mine havent drifted in over 5 years since leaving connected to mains. What really needs to be done is re-cap the unit and this should prevent any further issues once warm. But re-capping alos has its problems, lifting tracks due to excessive heat, incorrect temp caps etc

73's

Dave

I, too, recently received a TS-520 as a gift. Mine is in pretty good working order except the original owner had converted the three 10m band segments to CB by replacing the three 10m crystals. Apparently this was a fairly common mod, so if your 10m band seems to be full of noisy CB chatter, you'll need to replace the crystals. A dental mirror is a big help in verifying they're the right frequencies. Sometimes only one or two of the crystals have been changed. I ordered mine from International Crystal Mfg. A complete set of used 10m crystals can be hard to find and often are untested or guaranteed so I chose to buy new. Here's a link with more info:

UN- modifying a TS-520 (11 back to 10 Meter) [Archive] - QRZ Forums
http://forums.qrz.com/archive/index.php/t-391876.html

Also, be aware that the rig will power up but appear to be otherwise inoperable unless either an external VFO is plugged in or the back-panel external VFO socket has pins 8 and 9 shorted to each other with either a special plug or with a jumper wire. Here's a link with information on this:

Kenwood 520 - External VFO connector/plug [Archive] - QRZ Forums
http://forums.qrz.com/archive/index.php/t-310744.html

K4EAA's website has a good list of initial steps to take in restoration. My rig's performance improved dramatically after the cleaning and lubrication process in step 3:

http://www.k4eaa.com/steps.html http://www.k4eaa.com/steps.html

Good luck,

Bob

51528. Kenwood TS830M problem S-meter at the turn

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-03-13 16:27:58 UTC
From: alexanderlechner231@...
Topic: 51528 Message: 51528

Dear OM's!

My name is Alexander and I am from vienna.

My English is not so good :-)

I am the happy owner of Kenwood TS830M who has already brought me a lot of nice QSO.
The following observation I made quite some time.

When you switch the transceiver is noticed that completely refuses the S-meter to the right side and then slowly back to the left side goes back and at the same time then come the first signals. The time course is about 1 second from power on to rash and return to the normal position.

To configure z.Bsp. Voted 40 meter band, Drive Plate and load, then the phenomenon can be seen that deflects turn the S-meter fully in.

But if the drive controller is not matched to the 40 meter band (or the other bands) is not a full scale display or not as extreme.

If z.Bsp. the transceiver is tuned to the 40 meter band and I in front of the switch on the 20 meter band with the band selector switch, the S-meter does not go to full scale.

Maybe one of them had the same problem, and I am grateful for every tip.

Thank you in advance

51529. 820s Tune up problems

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-03-13 18:30:30 UTC
From: joe.mckeownaa@...
Topic: 51529 Message: 51529

Hi,

Hand me down TS-820s and relearning my hybrid skills from 30 years ago...

Meter readings:
Plate Idling current= 60ma
HV=900v

In tun mode, with car gain at 10 o'clock:
Can peak drive in ALC box. Any more Car (beyond around 11 o'clock position) causes drive control to peak beyond alc box on meter. Very hard to turn down drive control and stay in alc box on meter if car control more than 10 o'clock.

Switching meter to IP and adjusting plate causes meter to deflect to the LEFT onto the pin. This is the major concern.

Switching mode to CW allows for plate dip, load adjust and looks to be putting out about 95 watts at 200ma IP into 50ohm dummy load. At 225ma about 100 watts output.

This radio is sentimental to my family, and in beautiful cosmetic shape, so want to make sure we take good care of it. Receive is good, and the digital display works most of time. Tends to flake out if left on for too long.

I cleaned it up and lubed up the mechanical parts but have done no other work on it.

Any suggestions/concerns from the hybrid lover community? Rig could probably use a good alignment at some point, but no time or tools to do that right now...

Joe

Hello-
I need the TS-511S operator and TS-511S Service manuals. Would like to get VFO-5SS and PS-511 manuals, too. All of these manuals are to go with a very nice TS-511 station I am going through.
I need manuals that are very good scans from originals; the TS-511 operating manual that shows up all over the net is, IMHO, a poor copy.
Thanks all!
Byron WA5THJ

Thanks very much, Bob. I have an 820 that I bought from my Uncle a couple of years ago, so thankfully I'm pretty knowledgeable about it. Hope to transfer that knowledge to the 520 this weekend. Your suggestions are great, so I will check that out.

Looks like it has a perfectly nice plug in the back of it. I should be able to use it on the 820, too.

I need to work on some tax junk this weekend... but I am ABSOLUTELY going to do all that I can to see if I can get this 520 resurrected sometime tomorrow!

Hope everybody has a great weekend. 73,

Barry

Thanks Dave!

I was able to open up the unit, and reseat the plug-in connectors.

The unit does still exhibit the below symptoms, but takes a few minutes longer to develop.

When cold, and first tuned on, the VFO acts normally.

Both slow and fast tuning are correctly displaced on the digital readout.

The digits climb and fall, based on the rotation of the tuning know.

After 5-10 minutes, the process is not stable.

That is, slow tuning does move the frequency up or down correctly, but when I speed up the turning process, the display does not advance accordingly.

In other words, after warm up, if I rotate the dial one full rotation in a second, I get good tracking.

However, if I speed up the rotation, the digits do not climb, nor fall with the faster speed.

And, if I turn the dial ~2 rotations every second, the frequency jumps around where I was before I started to rotate.

Do you know if there is a common problem area I should focus in on?

If I need to remove the VFO and blow dry air into it, is the removal process the same as the TS830 (which I've already done).

Thanks in advance for your kind comments.

Tom,

What your describing is exactly what numerous others have suffered with. It Is the electrolytic caps that are failing. So apart from leaving connected you would have to replace than all. I would go as far to say if replacing I'd go for 105 degree type. Most problems are on the power supply.

The vfo230 does not have a vfo it has an optical encoder, this very seldom gives a problem apart from a little dust build up. But will not give the symptoms you are describing . Have you tried leaving connected to power 24 hrs.

Joe,
The plate idling current and HV are just fine.
What you are seeing regarding the ALC reading is normal. Many new(er) owners get scared/confused by this...all you are doing is adjusting the "drive section" to proper resonance/alignment...the reading is not important at this stage. If you can get full deflection of the meter with a low "CAR" setting that's a good sign...it means that your driver tube is functioning well...especially is you get full swing on 10 meters.

The next item is a bit confusing. Are you saying that the meter deflects to the left of the "zero" resting position...or just doesn't move up scale?I take it that the meter select switch is still in "tune?"
You know that you have Ip because you can tune to 100W or so in the CW mode as you stated later in your post.
The possible problem maybe the voltage divider resistors on the HV(high voltage) board...R-5 & R-6 (56k each). When the mode switch is in "tune" only about 50% of the usual high voltage is supplied to the final amplifier board/tubes so as not to run the unresonant final amplifier circuit/tubes at full high voltage and cause final tube damage.It is not unusual for one or both of these resistors to go high in value and reduce the voltage even more. Usually this is seen first in the "no ALC in tune" scenario. You can do a basic voltage check on the offending resistors by measuring the voltage at the "TUNE" post on the HV board. BE CAREFUL HERE...you are just 1/4 inch away from about 900VDC...which WILL really ruin the rest of your day...as in SK

Several high quality operators & service manuals, and proper tuning instructions are available from several group members: Mike: w5rkl "dot" com and Terry: k9tw "dot" com you can also go to k4eaa "dot" com and download a high quality large format schematic of the 820(s)

Thanks again Dave.

Do you mean the electrolytic caps in the power supply area?

Specifically, C2, C3, C4, C5, C6, C7, C11, C12, C14, C15, C16?

And, even then, there's no assurance that indeed this is the problem right?

Hi Joe,

Thanks for your response. I'll check out the links to make sure I am doing this right. I do have owner and service manual and that is what I was reviewing.

I understand the ALC readings, but am perplexed on the IP reading when in tune mode. The meter at rest sits above the "0" position, reading just about at the 15ma point when nothing is happening (so the meter itself is a bit off....)

However, with mode switch continuing to be in Tun, meter set to IP, activating the send switch causes the needle to move left to the 0 position, making it hard to dip the plate in tun mode.

The plate dips just fine in CW mode, so maybe it is the resistors. But I want to learn a lot more before I get anywhere near 900VDC!

Thanks again for your thoughtful response..

Joe

Tom

Without isolating each cap that is out of spec is a hit and miss affair. Predominately the power supply had shown the highest number of failed caps. But unless one is prepared to go through each cap methodically it is purely a hit and miss affair. Again you have to be cautious in continually heating the foil tracks as these lift with too much heat

Bill,
The correct term is "modulate."
Who is telling you that your audio is distorted...or are you listening to an audio sample using the "mon" function?" Is it on both USB & LSB?Does the receive audio sound good and clear? Is this radio new to you? Are you using the proper setting of the of "mic" control in association with the ALC reading to properly set your audio input?

There are NUMEROUS possible problems: maladjusted TC-2 or TC-3 on the PLL board, bad/miswired/incorrect impedance microphone..I also recall a group member had a similar problem and it was a poor connection on the VCO cable... or bad filter caps...etc...etc. Bad ground connection(s) on the AF/AVR board.

What is your level of knowledge and what test equipment do you have available?

I was also very disappointed in the color match from the mentioned
ePay seller. I even bought another can figuring there must have been
a problem with the first one. Nope, they were both way off shade.
That's when I went to a local paint company and started ordering my own paint.

The problem getting can's to other countries is the paper work and
only certain carriers allowed them. In the US they needed to be
shipped via USPS ground. Could not do Air.

Good luck,
Mark, WB0IQK

51554. RE: [TS-520_820_530_830] Re: Kenwood Paint

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-03-14 19:47:03 UTC
From: Joe Wolfe
Topic: 225 Message: 51554

I **think** the person inquiring is from Great Britain, probably don't have an O'Reilly's there. J I suspect they have many house paint stores and there they can get a computer read on the chassis paint color. Don't know if auto paint stores have that capability, but the auto paint stores can put the color in a rattle can.

Joe – W7RKN

From: TS-520_820_530_830@yahoogroups.com [mailto:TS-520_820_530_830@yahoogroups.com]
Subject: Re: [TS-520_820_530_830] Re: Kenwood Paint

Like Keiths story, I would go to the local O'Reillys Automotive store and they would match the color that I supplied and put the paint into an aerosol spray can. They were actually quite good at the color match.

51555. Anybody have a RadioShack parts list we should look for while on sale?

Yahoo group: TS-520_820_530_830 (2015 — 2016)

Topic: 51555 Message: 51555

I was in a closing RadioShack today and wondered - does anybody have a list of parts/components that we ought to look for while their sale is going on? Capacitor part numbers, etc.?

I bought some cable and other stuff, but I wasn't sure about any internal parts, so I figured I would ask the experts what you stocked up on. I know their cables aren't phenomenal but a 20 footer for $3 I couldn't pass up.

51556. Shure 444

Topic: 5605 Message: 51556

does anyone know how to connect s Shure 444 [not 444D] to a Kenwood 830. - one wire to PTT, one wire to mic.....can I use the shield for the grounds of the PTT and the mic [i.e. pins 3 and 4] ?? I don't have the mic yet....I will get it Monday. Someone suggested I may get a hum.
The alternative is to get a new mic cord and rewire the 444

Bill,
I read your other off list msg to me. You answered a couple of questions that needed answers..ie using the MC-50. I doubt that you have HV problems as you stated(off list) that you can get a good 100W output on 40M.
I suggest that you get a good clear copy of the 830 Service Manual.Several places...and they're free to download: n6wk"dot"com andw5rkl"dot"com. Go through the manual and identify the items you'll be working on. You can do a an initial quick check by checking first item #1 on Pg 33 of the Service Manual...then check frequencies noted in item #3 on same page. I do recommend that you do check as many items as possible in the manual...as you do not know if the "Golden Screwdriver" has been at work.
I'll help you as much as I can Bill, but I'm not an expert on this. Hopefully, Terry-k9tw or Mike- w5rkl is reading this, as they are much better than me

51564. Hybrid Net Update (March 15, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-03-15 19:21:02 UTC
From: Mark Gilger
Topic: 51564 Message: 51564

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by Mark,
WB0IQK. There were 26 stations checking in under good band conditions.

We had the following number of radios checking in.

1 running TS-520(x)
4 running TS-530(x)
7 running TS-820(x)
7 running TS-830S
0 running TS-510
0 running TS-511
1 running 599 twins
0 running TS-900

I was running my TS-830 + Drake L-4B amplifier.

The Sunday net was run by me, WB0IQK. There were
16 stations checking in under fair band
conditions. We had the following number of radios checking in.

4 running TS-520(x)
1 running TS-530(x)
1 running TS-820(x)
2 running TS-830S
1 running TS-510
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-940S + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome

as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total = 142, Sunday☐s total = 88
December 2014, Saturday☐s net total = 92, Sunday☐s total = 86
January 2015, Saturday☐s net total = 110, Sunday☐s total = 84
February 2015, Saturday☐s net total = 103, Sunday☐s total = 98
March 2015, Saturday☐s net total =44, Sunday☐s total = 28 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Joe,
No problem...the majority of us here ALWAYS warn about the very high voltages...kinda of a standard disclaimer...hihi
It is also very common to see the "S" meter sitting above the "zero" line. This is usually easily taken care of by adjusting VR2 on the IF board to the "zero" point(step 21) in the Service Manual. You can cheat a bit on the "S-9" (VR3 on the IF board)setting by using the calibrator signal instead of a signal generator(if you don't have one)...to get in the ball park after setting the meter to "zero" with VR2. It's relative anyway.

Also, check for the proper resting point for ALC reading of the meter by looking at Step 17.

Dave,
How have you determined that the VFO is 50kc off, and what do you mean that the VFO is "touchy" when it's close to a signal?
Everything you need to know about removing the VFO is contained in the Service Manual...mine shows VFO removal on Pg 8, Section 3-5.
Check that the VFO's frequency spread(tracking) is properly set...look at Pg 14, Section 3-21of the Service Manual

From: W5RKL
Topic: 51566 Message: 51569

The TS-520 doesn't have a PLL, it's a simple heterodyne conversion
transceiver.

Hi Dave and Wes,

Is the VFO tracking off the same amount on all bands? If it's off on one
band but not others then it's quite possible that band's band switch
selected heterdyne crystal is off frequency. The VFO itself doesn't
determine the transceiver's operating frequency. The VFO mixes, in
transmit, with the 3.3xx.x Carrier Generator signal to produce the
transmitter's 8Mhz TIF signal that's applied to the transmit mixer on
the RF Unit where it mixes with the band switch selected HET OSC crystal
frequency to produce the actual transmit frequency applied to the driver
and final amplifier. The opposite is true in receive, the receive signal
mixes with the band switch selected HET OSC crystal frequency where it
produces the receiver's 8Mhz "RIF" signal. The 8Mhs RIF signal is then
applied to the VFO Mixer on the IF Unit where it produces the 3.395Mhz
IF frequency.

The VFO is common to both transmit and receive but only at one point in
the receive and transmit signal process stages. This can be seen by
studying the TS-520's Block Diagram which shows how the VFO plays it's
part in the overall scheme in things.

51571. 3SK22 in R-599

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-03-16 04:07:28 UTC
From: Byron Tatum
Topic: 51571 Message: 51571

Hello-
This message may be a little off-topic since it is in regards to the R-599 receiver however the 3SK22 device is used in some of the TS-520 units.
Can anyone in the group take a few minutes to enlighten me on the 3SK22 DG FET? I ask this as I am working on several pieces of vintage gear that use this device (Kenwood R-599 receiver for one).
I am a little confused about how the 3SK22 compares to later DG FET's such as common 40673, etc. I notice how the 3SK22 schematic symbol is drawn differently, and it is not referred to as a MOS device.
Can the 3SK22 be replaced with more recent devices such as the 40673, 3N201, 3SK40, etc? I do work a lot with the DG MOS devices, but have done little work with devices like the 3SK22.
One of the reasons I ask is that I am curious if I can improve the performance of my R-599's by substituting more modern devices, particularly for the mixers.
Thanks, Byron WA5THJ

51572. TS830s - instability on CW transmit

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-03-16 11:26:35 UTC
From: gm0hks@...
Topic: 51572 Message: 51572

Hi, my 30 plus year old TS830s has started to exhibit some instability on CW transmit and was wondering if someone would be kind enough to give me a "heads up" as to potentially what it might be and where to start troubleshooting. I first noticed that a station I was working appeared, on receive, to be suffering from some form of instability as his received CW note was jumping a few hertz and altering frequency throughout the QSO. It was then that having moved frequency and worked another station with similar received results that I began to ask the question, is it my transceiver ? That station confirmed that indeed my transceiver appeared to be moving in frequency. Not a steady rate of drift but "jumping" in frequency. The only thing so far that I noted was that the FIX button to accomodate an external VFO seems "flaky" in as much that when I pressed it in and then out/off again, the received CW note from a station on 40 metres became "wobbly". Don't ask me how or why I discovered that, I just did. All I can say is that the issue is intermittent. I have been monitoring my transmitted signals on an SDR receiver facility in Central England and sure enough, from time to time, the VFO frequency seems to alter and the transmitted note similarly changes by a couple of hundred hertz !! In terms of listening to SSB transmission, the receiver remains stable and show no signs of altering frequency.

A starting point has been that I have "carefully" tightened the hold down screws on the RF board but I cannot see anything obvious at this point in time. A little guidance would go a long way. I appreciate I may not have supplied sufficient information for anyone to make a considered judgement on but a grateful thanks in advance to anyone who can sponsor an answer.

I cleaned it thoroughly with DeOxit, cleaned the contacts on the tubes, and the 520 fired up and receives well - but I cannot get any power out when trying to transmit. I even opened it back up and replaced the single driver tube, but that didn't do any good to try to transmit.

Looks like I better get a local to help me get this thing going. I have new final tubes, but I don't have enough expertise to try to neutralize them, so hopefully I can get one of the guys in a local group to help me out.

This 520 does receive well, though - it seems to be off a little with precise frequency/knob readings, but it receives well. At least it's not going to seem to be a big problem to get this one working.

Interest in the KV6O DG5 Emulator Boards seems to me waning. ? ? As mentioned on here previously, Steve designed a custom Arduino Shield Board and the software necessary to create a DG5 Emulator for the Kenwood TS-520S and made it open source. ? Steve does not run a business, but he has done several small production runs of his custom Arduino Shield board, and has made those boards available at a very reasonable price. ? His board uses all through-hole construction, not surface-mount construction. ?So, it is 'buildable'. ?;?

Steve reports that he is currently out of stock on the boards and he says that he does not plan on having any more made unless he receives enough interest. ? ? So, if you have been thinking about building one of these, you should probably put in an order with Steve now. ? Once Steve no longer supplies them, the alternative will be having a board made yourself from his open source design files, and that will certainly be more costly. ? ?

http://www.kv6o.com/wordpress/projects/kenwood-dg5-emulator/

Caveat: ?Steve designed this project specifically for his TS-520S. ?Once built, it is plug-and-play with a TS-520S. ? Since it is basically a buffered frequency counter with a display, it can probably be adapted to other models, but Steve is not interested in doing any adaptions. ?He does not have the other models available, and he has moved on to doing some new projects. ?Steve made this one open source to allow others to do the adaptions. ?

Disclaimer: This is being shared here 'for information only' - I have nothing to gain from sharing this. I have bought one of Steve's boards to build one for my TS-520S. ?;I have a box full of the parts needed, but I have not gotten to this project yet. ? So I cannot report on its performance. ? But the design has stabilized, and I have not heard any negative feedback from anyone who has built one.?

I would clean the VFO rotor shaft wiper contact. If that does not address the "touchy" operation then clean the AVR 9vdc regulated trimmer pot and the RIT trimmer pot.

If you decide to attempt the VFO alignment to correct the tracking issue be very careful. The drawing in the Service Manual is wrong. It has L1 and TC-1 reversed. L1 lead screw is secured with a heavy coat of locking paint and very easy to break off one of the tabs on the slotted head of the lead screw. Not sure why KW did this as the lead screw position is secured via a spring wire.

You may be better served to remove the VFO to free up the inductor core lead screw.

You might want to think about buying a remote VFO. Very useful accessory and might be cheaper in the long run!

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <stilesjoseph@...> wrote :

Dave,

How have you determined that the VFO is 50kc off, and what do you mean that the VFO is "touchy" when it's close to a signal?

Everything you need to know about removing the VFO is contained in the Service Manual...mine shows VFO removal on Pg 8, Section 3-5.

Check that the VFO's frequency spread(tracking) is properly set...look at Pg 14, Section 3-21of the Service Manual

Byron,
If anything, it is the signal-to-noise (S/N) parameter that would benefit, when you say "..improve the performance".
I'm just happy to get the RX working back to specs when I rescued a hybrid that I purchased DOA...
The NTE222 (about $12 ea) is a modern replacement, or one that's pretty close. I used a NTE222 for a blown/damaged dual gate MOSFET in a Tempo2020's RX board and it worked really well. I don't have the sophisticated test equipment to measure the S/N improvement, so your question is hard to answer, if there is an answer?

Wes, you're not an idiot.

Yes the TS-530 has a PLL system, as does the TS-820 and TS-830.

The 3 TS-520 models all have the same transmit and receive signal processing scheme.

It's important to determine whether the VFO tracking error occurs on all bands or only one or two bands.

If the TS-520 VFO appears to be tracking incorrectly, it's important to verify whether that tracking error occurs on all bands or only on one or two bands.

If the tracking error occurs on all bands then it's possible the VFO has been messed with or the mechanical dial assembly has been moved and not properly reinstalled during VFO maintenance by a previous owner.

If the VFO tracking error is on one or two bands only yet tracks properly on other bands then the problem is more than likely caused by the band switch selected Het Osc crystal(s) which has/have aged over time and should be replaced.

A touching/unstable VFO when tuning, is most likely caused by a dirty VFO variable capacitor shaft to frame flexible connection inside the VFO and most likely requires cleaning.

51579. RE: [TS-520_820_530_830] KV6O TS-520S DG5 Emulator Boards

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-03-16 18:08:52 UTC
From: David Boothe
Topic: 51507 Message: 51579

Jody,

I had interest in adapting the KV6O unit for my TS-820s, but decided another way (the AADE.com DFD2-820) was more practical and cost-effective, especially if I wanted to install the counter/display in the radio and not as an outboard unit in a box. My choices might be different than someone who wants to buy a DG-5 replacement to use with the 520, as per below.

I have wanted to install a more modern digital frequency counter and display on my TS-820S to replace the problematic DG-1 unit. I looked around and found three alternatives: 1) the KV6O Arduino-based design and 2) an adaptation of the Almost All Digital Electronics (AADE.com) DFD2 unit and 3) the DD-103 "digital dial" unit from electronicspecialtyproducts.com. Each of these units was originally designed for the use with the TS-520. My question was whether they could be used with the 820 series radios?

The DD-103 is an adaptation of the AADE DFD3 unit and comes fully assembled for use outside the radio. It will apparently work for the 820 and measures VFO frequency only and has to be calibrated for each band/mode. I also wanted a unit that could be integrated into the radio itself to replace the DG-1, so I didn't go this way. Cost is $125 plus shipping. You buy it, hook it up and set it up (for the 520-more involved with the 820).

The KV6O unit was designed and proved out for the TS-520 (see YouTube videos by toddfun.com, Todd Harrison). Steve Leander and Todd adapted some of the AADE approach in designing the front end of their unit. As with the DD-103, this was mounted in a box and used outside the radio. I corresponded with Steve Leander and he felt it could be adapted for the 820 series radios, but had not done this. The 820 radios handle VCO, Carrier, and VFO signals differently that the 520, but it looked do-able to me and could be probably built in a way to integrate into the 820S. I bought the shield (board) for the unit and, parted out, the cost looked to be something like $85-100 without enclosure depending on what you paid for the Arduino board. Programming the board would also be required, but everything was provided by Steve on KV6O.com, including parts list, excellent build instructions and the code.

I concluded that the AADE DFD2 unit was the most practical way to go for me, as Neil bases his design on a programmable counter that he can set up for specific radios. The DFD2-820 unit is specifically set up for the 820 series and with a small upcharge for a back-lit LCD display, was just under $60 including shipping. Unfortunately, Neil was ill and not doing business when I inquired, but has since begun supplying kits again, so I bought the kit.

I built it in an evening and it works with the 820S using the existing 5V and 14V feeds and the CVC and CCR inputs from the 820S used by the DG-1. The tricky part is getting the LCD display physically in place around the VFO and dial mechanisms, but it looks do-able.

I plan to update the group and put notes/pictures on the board if successful.

Darrell,
Both tuners will work with your 820S. Both are manual tuners and the BIG difference is that the 230 has WARC bands, the 200 does not. So, if you plan on getting a rig capable of WARC bands in the future...the 230 would be a better choice

Darrell,

The AT-200 and AT-230 are basically the same except the AT-230 has the WARC bands where the AT-200 does not.

They both have the same power rating, 200 watts, same input and output impedance, and both have the same in-line 20/200 watt meter.

The front panel FUNCTION switch on both tuners has a position labeled "DUMMY". Neither tuner has an internal dummy load, you must provide the external 50 ohm dummy load and connect it to the rear panel's "DUMMY" SO-239.

Both tuners are designed for "unbalanced" coax antenna feed lines.

You can download the manuals for both tuners at the following links:

AT-200
www.kg6haf.com/downloads/AT-*200*_Manual.pdf

AT-230
www.kg6haf.com/downloads/AT-*230*_Manual.pdf

You would be best to download both manuals and study them so you learn what each tuner's capabilities and specifications are.

Dave,
Ok, I understand. I would clean the VFO wiper, and the other 2 items as Terry-k9tw recommended. It's been awhile since I've had a 520...and I forgot about the schematic being wrong. I would still check the VFO tracking. If you decide to remove the VFO, the VFO wiper is much easier to clean. Also, must easier to remove the white threadlock on L-1. Go SLOW with a fine screwdriver or similar tool to remove all the stuff around the shaft...I would hesitate however to use some sort of solvent. The shaft is soft brass...and will get really messed up when treated badly...(the 820 has a similar VFO arrangement) I have some experience here...hihi

Based on your comments, it appears the cable has an intermittent connection at one or more of the pins inside the VFO cable plug. Have you tried to remove the plug's cover by rotating the cover CCW? Be careful and hold the pins end of the plug with one hand and rotate the cover CCW with the other hand. You will need to fix the intermittent wire to pin connection(s) otherwise the cable could easily cause the VFO-820 to fail again.

So I picked up a TS-520 yesterday. RX is there but most of the time the S-meter is in the 59+ area with lots of noise and oscillation. Only in WWV position the RX is normal. On all other bands RX is insensitive and oscillating. In TX nothing comes out on any band, HV is there, bias works but zilch on the AFC/RF/IP metering.

All tubes original, no mods. Clean radio.

Where should I start, bandswitches? Can't find anything about the best way to handle the wirewrap wiring to the boards, just snip it, try to unwind en rewind around the post, what are you all doing?

Dave,
If you have the front of the rig facing you, and the top off..look at the RIGHT side of the VFO...you will see a small "door" with two screws...this gives a little access to the inside. With a BRIGHT light...look inside at the far rear of the VFO you should see a small piece of metal.. a flat piece of spring metal...could be silver or brass colored ....that's the "wiper." Spray with cleaner/lube and run the VFO through it's travel several times...blow out with "canned" air...and repeat once. DO NOT mess with this piece of spring metal...no tools...PERIOD! It's kind of a pain to get to the wiper with the VFO installed..but it can be done...just loosen the front screw..and remove the rear most one...and pivot door out of the way

  Dave,
Ok, I understand. I would clean the VFO wiper, and the other 2 items as Terry-k9tw recommended. It's been awhile since I've had a 520...and I forgot about the schematic being wrong. I would still check the VFO tracking. If you decide to remove the VFO, the VFO wiper is much easier to clean. Also, must easier to remove the white threadlock on L-1. Go SLOW with a fine screwdriver or similar tool to remove all the stuff around the shaft...I would hesitate however to use some sort of solvent. The shaft is soft brass...and will get really messed up when treated badly...(the 820 has a similar VFO arrangement) I have some experience here...hihi

Joe/Jan:

He is placing different dual gate mosfets into the RF amp socket of his Yaesu transceiver front end. He then uses another transceivers low power transmitter output into a dummy load as a signal source. He is transmitting a test signal and not coupling it into the SO-239. He peaks the S meter reading with the VFO and the Preselector and the device (40673, 3N211 etc) that results in a higher S meter reading is declared the "winner". I am pretty sure Yaesu didnt build the RF amp and spec its gain controlled device in isolation.

He apparently does not own a calibrated RF Sig Gen, Spectrum analyzer, true rms Audio Voltmeter among other equipment necessary to measure Noise figure.

He has no clue if the increased S meter indication is due to the devices gain or due to its added noise contribution which by the way all devices have. You cant simply swap Mosfets without looking at the source resistors and other biasing aspects and circuit parameters.

It appears he is all caught up with receiver sensitivity. Not only is his method suspect he is missing important point. I submit in today's world of high power and high gain/directive antennas that are in common usage on all the ham bands (kilowatt alleys) he would be better served to be more concerned about a receiver that has excellent wide Dynamic Range.

That is what KW did with the design of the TS830 receiver. They selected a dual gate mosfet for the RF amp (3SK73) that has a little lower transconductance and low noise and followed it up with a Double Balanced RIF Mixer that has a very low noise figure. Too much gain typically means poor strong signal IMD rejection. The trick to address that is is using a good Balanced Mixer with low noise figure following the RF amp. You want a receiver that is very sensitive and has wide dynamic range and low noise level. As designed and built we dont have to worry about weak signal copy with our KW hybrid receivers. I understand that experimenting is the essence of the hobby for some but in this case nothing is broken. Our problem is what to sub when the original device is obsolete and unavailable and not so much about improving performance.

I dont have laboratory grade test gear, but I do have adequate service grade test equipment that allows me to measure MDS on each customers rig before and after alignment. This allows me to make meaningful comparisons of all the KW hybrid models that I see.

I have posted on this site before how to use a calibrated RF sig gen and a DMM (preferably true rms), and a 8 ohm dummy load at the ext speaker jack to make measurements and calculate the Signal-to -Noise plus Noise (S+N/N) ratio using a 1uv test signal and a calculator with log function to then calculate MDS. This method is more of an estimate but it is repeatable. Search on Conversations for MDS and should be able to find the procedure that I use. If you cant find it contact me off the list.

If he was doing this test procedure would produce more meaningful results.

Terry,

Thank you for providing a moment of clarity. I had been following the thread with some interest, and neglected to even consider gain vs dynamic range. As a DXer and contester I can attest dynamic range trumps receiver gain seven days to Sunday. I have taken my TS-530S into DX battle, and while it gave a good accounting of itself, I have plenty to of other radios that do a much better job. And you are correct in today’s competitive environment a radio with good dynamic range is a competitive advantage. Back in 72 when I was first licensed not so much, but today it’s an imperative. That is why I use my 530S (and my Drakes and Collins) for nets and casual operating where I can appreciate them for what they are. DX and contests go to the DSP/SDR radios to give me operating parity.

Again thanks for your sage observation.

Joe N9JR

Topic: 51571 Message: 51605

Thanks Joe.

I was trying to say that I didnt think that he had adequately defined the problem statement or devised and executed a reasonable accurate test method to validate the problem and validate any improvement from changes he made. I see this a lot today. It is all too common to publish anecdotal results or self-full filling results or "feel good" results.

The challenge for any receiver is that it must be able to operate in an environment where you are trying to copy a weak DX signal (S1 or S2 level) in the presence of two or more very close 20 to 30 over S9 signals.

As I mentioned front end RF amp gain isnt the issue with these old legacy receivers it is Dynamic Range ie overload from Blocking and/or Non-linearity from IMD producing phantom signals in the passband both of which can cover up our weak S1 signal. Also, reciprocal mixing and LO phase noise can greatly compromise receiver sensitivity and adding gain ahead of the Mixer wont address either of these two.

So if anyone wants to swap dual gate mosfet devices in your KW hybrid RF amp position have fun experimenting, but realize with exception of the TS520 series no sockets involved and not easy to do (I hate pulling molex connectors off boards, lifting PC pads and traces, inducing cracks at pin pad to trace junctions or inducing other latent failures) and again in my opinion adding front end gain is not the answer to chasing weak signal DX on very crowded bands occupied by operators running high power.

I dont have any first hand experience with the FT-301 performance, but took a quick look at its specs and it was not unlike the rigs of the day. It has sensitivity specs in the 0.2 to 0.5 uv range. To accomplish that it used dual gate mosfets like the 3SK35 and 3SK40 in Q-102 RF amp and Q-103 1st Mixer stages. As these FETs would get blown out from nearby lightning or accidental transmit rf it would be common to change them out with 40673 or 3N201 or NTE-222 or NTE-454 devices that have built in protection diodes. Nothing wrong with that if you cant find the original device.

I reread this fellows page and he not only plugged in different mosfets for Q102 RF amp he also did the same in concert for Q103 Mixer. I would never recommend changing both devices at the same time to higher gain mosfets. If anything I would only experiment with Q103 Mixer and I would look for a mosfet with a lower NF. All of the subs seem to have a NF that runs around 3.5dB to 5.0dB depending on test frequency which is high from 45mhz to 200mhz.

If anyone is interested there are numerous QST, Ham Radio magazine and various white papers and power points on receiver dynamic range and the writings of Rob Sherwood are worth reading as he even discusses how KW engineers addressed the blocking and overload issue with inclusion of the capacitive divider shunt attenuator between the RF amp and the RIF Mixer in the TS820S (on all the Hybrids accept the TS520). This circuit reduces gain from the RF amp on the low bands and allows full gain on 10 meters. It is diode switched via the bandswitch so no operator action is required. I believe I previously posted on it and how to identify and test it.

If you want to improve ability of your stand alone KW HF receiver to dig out the weak 10 meter DX signals and you have about $150.00 to spare buy a DXE RPA-1 pre-amp. Placing a good RF pre-amp ahead of the rigs RF amp can provide additional gain without increasing the noise floor. Read the Eham reviews.

OK more than enough of this. Moving on.

Terry K9TW

Dave
What rig are you talking about? Is it worn...or is the shaft bent from being hit/dropped while being shipped?
Either way removal of the VFO will be needed. The Service Manual for the rig you have covers VFO removal. The 530 & 830 series are the easiest by far...the 520 & 820, not so much. Gordon-n6wk(now SK) had a procedure of using a small diameter punch to dimple and push some metal towards the shaft. IF you are very adept at mechanical things, you could partly disassemble the offending parts and possible put a bushing in. The bearings(if it's a 530/830) are inside the knurled metal cap. It can be loosened...and some light oil applied from the end where the shaft enters. It's filled with grease from the factory..and gets hard/gummy. I have been successful in calming a rough VFO with just using the oil and then just snugging the collar back up

Joe;

Thanks for the input.

It is a 520, but with the 530 mechanical arrangement (i.e - three ball bearings and a 4th at the base of the inner shaft)..

It has been tampered with and the cap over the three ball bearings had been over tightened increasing the wear on the brass to the point when tuning, there is considerable chatter causing the VFO to jump in small movements.

I have taken it apart and cleaned all parts.

There was no lubricant of any type present, new or old. The upper race under the cap appears to be good; no scarring or wear.

It appears the wear may be too great to just tighten the cap some more.

Joe:

Yes in best of both worlds I would like to have one of the new high end DSP rigs as well as my beloved TS830s.

I have never had opportunity to operate one but I have looked at some of the specs. My old TS830s have stood the test of time, but if I was an avid contester no question the modern rigs can outperform it especially in todays operating environment.

I suspect I am too darned old to like or learn how to use all the myriad of features on a user selectable menu driven rig and wouldnt stand a chance under the hood. What would I do with 8 different AGC time constant setting options? I only recently figured out when to use Fast and Slow! The generation who grew up with computers probably love them.

Thanks and 73s
Terry K9TW

  Joe;

Thanks for the input.

It is a 520, but with the 530 mechanical arrangement (i.e - three ball bearings and a 4th at the base of the inner shaft)..

It has been tampered with and the cap over the three ball bearings had been over tightened increasing the wear on the brass to the point when tuning, there is considerable chatter causing the VFO to jump in small movements.

I have taken it apart and cleaned all parts.

There was no lubricant of any type present, new or old. The upper race under the cap appears to be good; no scarring or wear.

It appears the wear may be too great to just tighten the cap some more.

Either way removal of the VFO will be needed. The Service Manual for the rig you have covers VFO removal. The 530 & 830 series are the easiest by far...the 520 & 820, not so much. Gordon-n6wk(now SK) had a procedure of using a small diameter punch to dimple and push some metal towards the shaft. IF you are very adept at mechanical things, you could partly disassemble the offending parts and possible put a bushing in. The bearings(if it's a 530/830) are inside the knurled metal cap. It can be loosened...and some light oil applied from the end where the shaft enters. It's filled with grease from the factory..and gets hard/gummy. I have been successful in calming a rough VFO with just using the oil and then just snugging the collar back up

Topic: 51580 Message: 51613

Correct me if I'm wrong, the AT-230 is matched size wise (in height) to the TS830 NOT the 820. The AT-200 is a match for the 520/820.

Some people are particular about matching components in their station

Maybe a factor, maybe not

Hi Dave,

I had a 520 that had the same problem. I was
lucky enough with mine by backing off the cap
enough that the damage in the bearing track did
not affect operation. It wasn't perfect and I
knew the problem was still there but it certainly made the radio usable.

Lou and all;

Thanks for the input. I tried adjusting the tension but no joy!

I did finally find the problem and the drive is now operating smoothly.

An EXTRA ball inside the cluster!!!!!

Apparently someone who had worked on this radio before (evidenced by a couple of stripped screw heads, over tight cap etc.) added another ball to the center shaft, either because they thought they had lost one or???? This one had lodged in between 2 of the three outer balls.

When I was fishing out the center ball (for the Nth time)with a magnetized rod I use for fishing in mechanical situations such as this lo and behold, 2 balls came out

I re-greased everything and put it all back together AGAIN!

Moving smooth as silk, more or less.

Again, thanks to all for the suggestions.

Dave, W5WP

Hi Doug here. Im looking for the VFO assembly its self. # X40 1110 00
Also looking for the panel piece that sits in front of the VFO it has 4 screw holes on the corners and a clear window on top of it. If it is very good shape with no finger wear marks etc.
I am not interested in the VFO knob.
And the carrier assembly # X60 1000 00
I will offer you $55.00 for all of that.
Thanks

Hi Doug here. Im looking for the VFO assembly its self. # X40 1110 00
Also looking for the panel piece that sits in front of the VFO it has 4 screw holes on the corners and a clear window on top of it. If it is very good shape with no finger wear marks etc.
I am not interested in the VFO knob.
And the carrier assembly # X60 1000 00
I will offer you $55.00 for all of that.
Thanks
Doug

Eric,
I would first try and get some tuner/switch cleaner into the WWV/JJY pushbutton switch...and exercise it numerous times...and then maybe some more cleaner...and see is that helps. It's been a long time since I've been inside the 520. Mike-w5rkl(group member) has one and maybe can lead you down a more direct road.
As far as the wire wraps go..you'll break more than 50% even using a proper tool...those wires have been wrapped up like that for close to 40 years! Many times is you are lucky to get them unwrapped....they break while you're trying to re-wrap them. You may be able to possibly pull some slack to remake the connection(s)...but have some wire and shrink tubing..just in case

Never want to try to use any of the bare exposed unwrapped tinned conductor over again.

That means no attempt to re-wrap and no attempt to tack solder any portion of that old conductor. When a round wire is wrapped around a sharp square corner of the post it bites into the wire and makes a crease in it and it forms a gas tight connection. The wire is also work hardened in the process at that junction making it susceptable to breaking if you move it. Same as if you nick any solid conductor when prepping it for termination.

Seldom enough lead wire available to pull up and skin to all new bare conductor of sufficient length to re-wrap even if you have appropriate wire wrap hand tool for the gauge.

Best to re-terminate by cutting off all the old exposed unwrapped conductor and skinning back to a short piece of new tinned conductor and then lightly sanding the top of the terminal post to brite metal to remove oxidation and then make one turn wrap and tack solder. The higher up on post you solder less likely to put too much heat into the post to board solder junction and makes it easy to remove again if needed.

Hi group,

I have recently acquired a Kenwood TS-520S which is going well. However, today I pulled the covers to check inside and found a crystal in the FIX position. It is marked 5.323500. Is there an easy way to determine the transmit frequency? I have tried working the formula from the user manual "backwards" , but I keep getting fouled up! Thanks in advance.

John

Hi John,

What is getting messed up? The crystal takes the
place of your VFO in FIX mode. It's like leaving
the VFO on one frequency and switching bands.

Try this. Say you wanted to operate fixed on 20.

From the table in the manual we see that X = 14.0 for the 20m band

The formula is; 5.5 + X - Crystal frequency
OR 5.5 + 14.0 - 5.3235 = 14.1765MHz

Now try it for 80m

The formula is; 5.5 + X - Crystal frequency OR 5.5 + 3.5 - 5.3235 = 3.6765MHz

Of course this is for CW. If you want to work it
out for LSB or USB then you have to add or subtract 1.5KHz from 5.5MHz.

For LSB use 5.5015 and for USB use 5.4985

Hope that helps?

Lou

Topic: 22402 Message: 51631

John,

It depends on the band switch setting and MODE switch setting.

Go to page 24 in the TS-520 manual, page 23 in the TS-520SE manual, and page 20 in the TS-520SE manual.

Notice for CW the calculations start with 5.5Mhz. However, for USB, you start with 5.5015 and LSB with 5.4985.

The following example uses 40 meter (7.0 on the band switch knob setting).

Lets do CW first:

1. 5.500 is added to the band switch setting, 7.0 in the case for 40 meters. This gives you an answer of 12.5.
2. Subtract the crystal frequency, 5.3235 in thise case, from 12.5 which gives you an answer of 7176.5Khz or 7.176.5Mhz.

Lets do USB now:

1. 5.5015 is added to the band switch setting, 7.0 in the case for 40 meters. This give you an answer of 12.5015.
2. Subtract the crystal frequency, again 5.3235 in this case, from 12.5015 which gives you an answer of 7.178Mhz

Last, lets do LSB:

1. 5.4985 added to the band switch setting, 7.0 in this case for 40 meters. This give you an answer of 12.4985.
2. Subtract the crystal frequency, again 5.3235 in this case, from 12.4985 which gives you an answer of 7.175Mhz

The same crystal will work on ALL bands. You simply replace the band switch setting and use the same figures shown above.

The crystal operation is as follows:

If the FUNCTION switch is set to FIX, then the one of four selected crystals replaces the VFO in both transmit AND receive, crystal control in both transmit and receive.
If the FUNCTION switch is set to VFO-R, the crystal replaces the VFO in transmit ONLY, VFO tunes the receiver.
If the FUNCTION switch is set to FIX-R, the crystal replaces the VFO in receive ONLY, VFO tunes the transmitter.

You welcome John.

Just keep in mind that the band switch figure is always the value of "X" when calculating crystal frequency or calculating the operating frequency based on the frequency of the crystal. You also need to understand that one of the four selected crystals determines the TS-520s transmit and receive frequency based on the FUNCTION switch FIX settings.

Frequency control feature based on the FUNCTION switch FIX settings:

VFO-R means the VFO controls the receive frequency and the selected crystal controls the transmit frequency

FIX-R means the VFO control the transmit frequency and the selected crystal controls the receive frequency

FIX means the selected crystal controls both the receive and the transmit frequency, the VFO has no control over the transmit and receive frequency

VFO means the internal and/or external VFO controls both the transmit and the receive frequency and the selected crystals has no control on the TS-520 transmit and receive frequency

Hello,

I have a Kenwood TS-520 and I need to rewind it's power transformer. Can someone please share the voltage and current ratings for the different winding on this transformer. Also what core does this transformer use. I measured the dimensions of the transformer in my rig as 11cm x 9cm x 5cm.
Thanks in anticipation.

You can send it to http://www.heyboertransformers.com/

Call them about a rewind or replacement. Great people to deal with.

Robert.

You can also contact Gary at Transformer Rewinding Service and I'm sure he can help you.
http://members.tripod.com/tubes_tubes_tubes/transformerrewindingservice/
http://members.tripod.com/tubes_tubes_tubes/transformerrewindingservice/

I just sent Gary a filament transformer from my SB-221 to rewind. He came VERY highly recommended to me so I called and talked to him. He's been doing this for a long time and really knows what he's doing.

Thanks a ton for the information and your mail Robert. I am based in India and I am trying to get the transformer rewound locally. There are many competent transformer winding shops here and all I need to do is provide them with the voltages and current ratings of the various winding on the transformer.

I would really appreciate if this information can be share by anyone.

Thanks and regards,

There are a couple of power transformers on eBay. TS-830 and TS-530 for $37.50 each. I suspect that they would work but others may already have experience with a burned out TS-520 transformer.

Just search "Kenwood power transformer" on eBay.

Hi all, I have been using and loving my (new to me) TS-820s. So much so I want to buy a second one. Mostly so I don't have to always switch bands and retune. Looking at for sale sites, ebay, and other areas I can pickup many different 820's but I also see 830's. I want something that does not fold back power, and sounds great like the 530 / 820 do.

I have already picked up a VFO-820, sp-230, sp-820 and a at-200 (lost out on the at-230)

I am limited to 10 to 40 meter in my condo. I also do not see any digital or CW use, just SSB.

What if any reason would I want a 830's? I think it's newer but is it better? Newer is not always better these days.

Hi, Darrell.

I have both radios and love them both. Off the top of my head:

-The radios are about 5 years apart in vintage, with the 830S being the newer of the two.. The 830S was the last and most advanced of the famed Kenwood Hybrid transceivers

-The two share many features, with the 830S being more advanced in design with the following features that the 820S doesn't share: a) Variable notch filter b) XIT in addition to RIT c) Variable bandwidth tuning, d) WARC bands (30, 17 and 12 meters) e) variable level noise blanker f) an audio tone control on the front panel.

-The 830S has a dual conversion receiver, while the 820S has a single-conversion set up. I think both are great receivers and the differences aren't obvious to my ear.

-Both rigs use 6146B finals and a 12BY7A driver with similar output. The 830S drives the tubes a little harder in terms of plate current but neither rig, to my knowledge, folds back power like a solid state rig. The power amplifiers are very similar, but not identical. Both perform very well and both have outstanding RF-based speech processors.

-Both have fine audio on transmit and receive.

-The 820S had an optional DC power supply that connected through a plate on the back of the radio

-The 820S has FSK as a selectable mode, the 830S does not. The 830S has selectable "CW wide" and "CW narrow" modes, but you need the optional filter for CW-N to work. You can install an optional CW narrow filter in the 820S, but once it's installed, it's always active when you select CW mode (I believe)

-The 830S has dual IF connections in back that can be used for station monitors, band scopes, panadapters, etc.

-The VFO frequencies are different, so you can't share outboard VFOs between the two. The 820S can share with the 520S, and the 830S can share with the 530S.

-The 820S is battleship tough in build and was sold as a very high end unit (I have read that the original list price was around $5000 in the mid 70's!). The 830s is built (relatively) a little lighter and economically as was marketed as "more affordable", but it is still a very robust transceiver.

-The 820S was plagued with issues on the DG-1 digital readout, mainly due to poor soldering of the two circuit boards. These problems can sometimes, but not always, be resolved by re-soldering the boards and replating the through-holes ("vias"). No such issues with the 830S.

I invite others on the board can correct any errors or omissions-there are many here who know a lot more than me.

If I had to pick, I would take the 830S because of its more advanced features and the WARC bands, but then again I don't have to choose!

I hope this helps, Darrell.

Dave

Subject: [TS-520_820_530_830] TS-820s or TS-830s

Hi All, (sorry if this is a dupe post, I wrote this up a few hours ago but it never got posted so I wrote it again) I am having much fun with both HF and also my 'new to me' TS-820s. So much fun I want to get a second one so I don't have to keep switching bands and re-tuning.

I have already bought a VFO-820, SP-230, SP-820 (damaged-needs grill), and AT-200

I am only using 10 to 40 meters on SSB only no CW or digital modes.

I am wondering, if it was you. should I buy another TS-820s or a TS-830s? Other then more bands what is better if anything about the newer model? If not not these two then what model? I want something with the punch of the 820 that wont fold back power and has great audio.

David,

You have the price of the TS-820S in the mid-'70s a bit on the high side! The "street price" of the TS-820 (predecessor of the TS-820S) was $830.00 in 1976 from Burghardt Amateur Radio. The DG-1 digital display kit option (user installed) was $130.00. The TS-820S was the TS-820 with the DG-1 factory installed. Also, I believe when you owned a TS-820, and installed the DG-1, you effectively had a TS-820S, except for the nameplate difference. Earlier units of both did not have the spinner VFO knob, and later ones did.

Hi Neil,

I'd start by looking at the connectors inside the transverters. You will have to make your own multicore as it is very unlikely that you will find suitable multicore on a roll that you can purchase per metre.

Follow what the manufacturer has done, use coax where they use coax and hook-up wire where they use hook-up wire. From the service manual for the 502 it looks like you'll need two coax runs and perhaps seven hook-up wires.

For coax I would use RG174 or RG316 - you can get RG174 from Jaycar and MiniKits have both types. For hook-up wire I prefer Altronics over Jaycar. Work out how big the bundle is and find some suitably thick coax to strip for the sheath. I reckon it might all fit very snuggly inside a length of RG213 coax outer.

For our American colleagues, Altronics and Jaycar are electronics specialty stores in Australia that stock plenty of good stuff for the ham builder.

Regards

Lou

Thanks Lou Already got a 50mtr roll of rg 174 coming for other jobs as well, I was thinking of 2mm 7 core trailer wire might do the job so I might give it a go. The rg174 only goes into one plug at the radio and a lead to go from the 2mtr to 6mtr transverter for the RF. Some of the pins in the plugs don't get used according to the TS 520 manual, I looked at some pics in this groups photo section that looks like original Kenwood leads. I'm just happy to have the plugs to do the job, came from a VK4

Date: 2015-03-23 13:13:22 UTC
From: Mark Gilger
Topic: 51650 Message: 51650

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by Mark,
WB0IQK. There were 14 stations checking in under good band conditions.

We had the following number of radios checking in.

3 running TS-520(x)
1 running TS-530(x)
3 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
1 running TS-900

I was running my TS-830 + Drake L-4B amplifier.

The Sunday net was run by me, WB0IQK. There were
16 stations checking in under fair band
conditions. We had the following number of radios checking in.

4 running TS-520(x)
0 running TS-530(x)
0 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-940S + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome

as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total = 142, Sunday☐s total = 88
December 2014, Saturday☐s net total = 92, Sunday☐s total = 86
January 2015, Saturday☐s net total = 110, Sunday☐s total = 84
February 2015, Saturday☐s net total = 103, Sunday☐s total = 98
March 2015, Saturday☐s net total =58, Sunday☐s total = 44 (Month to date)

Greetings to the Group.

I have a very decent looking and operating 830s for sale. Everything works fine on the radio, with output well over 100W, at least according to my meter, with the original tubes. It even has a cw filter, although which one I'm not sure, .. but it is narrow..

The MODE switch has become loose. I haven't pulled the panel in order to see what needs to be done for tightening. The switch functions fine.

I thought to make the rig available here on the reflector first. If someone is interested, please contact me off of the mailing list.

Lastly, I really do not want to ship and will treat a deal for pick up with priority. Also, I'm wanting a late model Yaesu FT-857D if someone has one.

Thanks

51653. VFO Board

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-03-24 16:24:39 UTC
From: rrmvargo@...
Topic: 51653 Message: 51653

Hi Everyone,
I recently decided to try a VFO stabilizer in one of my 830S's (2M SN). As I was trying to follow the instructions I found that the board inside the VFO is different than shown on the stabilizer instructions. The instructions show the board that is on the schematics & service manual PDF's I have. So it appears I have a version not found in any documentation I have. Interestingly enough, the board does have X40-1170-00 it. On the foil side of the board it has J25-2765-14. Does anyone have any info on this board? I know someone was inside this VFO a couple of decades ago as it has a date marked on it. BTW, I still haven't been able to get the stabilizer to work on it. And the older 1M SN parts unit I have, has the VFO board as shown in the service manual. I did post a pic of the mystery board in the photos section. Thanx - Bob

If you can't figure it out, tie the output direct to the main tuning cap. I had an 820 that I had to do that with and it worked just fine.

So find the output from the vfo, that goes to the input of the stabilizer. Tie the output of the stabilizer into the main tuning cap. Done.

By the way, which one did you purchase?

Good luck,
Mark, WB0IQK

Topic: 51653 Message: 51656

Thanx, Mark,

I figured out where to tack it in, that wasn't the issue. I am just curious about the VFO board itself. It seems to be an inferior & early VFO board. eg- there are no insulator stand offs between the board an VFO bracket. The silk screening is better on the documented board and overall appearance just seems better.

I bought the K4DPK stabilizer. I increased the 2.2pf varactor coupling cap to 8.0pf & resoldered a wire leading to the air variable cap & it seems to be working now.

Is there a better Stabilizer board out there?

Thanx, Jim. I have seen the Cumbria version also, but thought it's be easier dealing locally.

Phil was pretty responsive to my emails & always maintained the concerned seller attitude, which I appreciated. I think K4DPK stabilizer is working well now.

Main culprit was a bad solder joint on the variable cap, I believe. The stabilizer was the last thing I wanted to do my this TS-830S. It is a pleasure to listen to & I get very good audio reports on it. - Bob W8RMV

From: gigahacker@...
Topic: 51660 Message: 51660

All, I just bought an AT-200, the switches need some cleaning but the tuner seems to work as it should. I have three antennas one of which is flat match and does not need a tuner. I was wondering if there is any reason why I can't hook that to the dummy load connector, making it THROUGH antenna 4.

The prints in the manual show it as the same as the other three selection other than the tuner is not connected.

I know I could use an external antenna switch but why if this works.

I invite your feedback

Topic: 51653 Message: 51661

The kit came with a 2.2pF & I installed a 8pF after I couldn't get it to work. Phil recommended a 5pF but the 8 was the closest I had. 82pF sounds like an order of magnitude too big.

But as I stated previously, I think the big issue was the bad solder joint on an unrelated wire to the variable cap. In fact, I probably could have solved a lot of the drift had I found the bad joint earlier and maybe not had to buy the stabilizer. Somehow I never checked that critical connection.

Anyway, my 830 is very stable now. - Bob W8RMV

Darrell,
Congrats on your purchase

There is no reason you can not do that...except if you don't want to.But ask yourself this...when changing bands..etc...how are you going to tune up? Good amateur practice would be into an appropriate dummy load...which means..either another external switch..or changing coax leads. 73 Joe

Darrell,

Yes, the AT-200's rear panel "DUMMY" connector, when selected by the front panel's "ANT" switch, is a straight through connection from INPUT to OUTPUT. The Band Switch setting has no affect nor does it play a role when selecting the DUMMY selection. Therefore, as you ask, you can connect your resonant antenna, no tuning required, to the rear panel's "DUMMY" SO-239 and select "DUM" on the front panel's "ANT" selector.

I would use the dummy-load connection to go to an antenna switch, put the dummy permanently on one output of the switch and the other to the flat-matched antenna. That way, I could tune up to the dummy load, OR (with the flip of the one extra switch) run on the 'fourth' antenna. Best of both worlds for the cost of one extra switch and one more coax patch stub.

The 2 position switch's "input" is connected to the transceiver while
the 2 position switch's Output #1 is connected to the 50 ohm dummy load
and Output #2 is connected to the tuner's input.

Check the following eBay ads for coax, PL-259s, UG-176 coax reducers, 30
feet of RG-8x coax (no connectors), a 50 ohm dry dummy load, and premade
jumpers if the owner doesn't care to build their own jumpers.

An MFJ-260C 300 watt dry 50 ohm dummy load is being sold under eBay ad
#301573952538 for $39.95 plus $10.95 shipping

A 2 position RF switch being sold on eBay ad #400760665003 $26.95 "Free
Shipping".

AneBay seller is selling a 10 pack of PL-259s with UG-176 reducers for
RG-8x for $19.95, Free Shipping, under ad #321457285684.

An eBay seller is selling 30 feet of RG-8x (no connectors) under ebay ad
#181697524552 for $13.50, Free Shipping.

A pack of six 3 foot RG-8x premade coax jumpers are being sold under
eBay ad #381199474908 for $23.95 plus $6.16 shipping

Unfortunately as built quality is an issue with all the Kenwood Hybrids especially when it comes to soldering both on PC boards and at air variables, parasitic suppressors, antenna connectors etc. I have numerous pictures I could share with you.

I dont know if any better or worse thanYaesu or other radio manufacturers of the period.

It is something most owners would not suspect as the root cause of operational issues. If you go to Ken K4EAA website he shows a picture of a solder joint that was missed at the factory. So good visual inspections are a must with most troubleshooting efforts.

As to differences in the VFO PC boards you will find that the -04 and -14 series boards are the most common and one of the changes will be relative to the number and kind of temperature coefficient capacitors that are installed. Will commonly find none, Black dot (NPO), Red Dot (Type N80) and a few other Type Ns. You should notice multiple parallel pc pads and some of them will have no capacitors installed in them. These are provided so that two to three Temp Coefficient caps can be installed in parallel to provide parallel paths for the RF current and reduce amount of heating that any one capacitor would see. Heat changes the capacitance value.

All of this is done at the factory as part of the procedure to stabilize the VFO drift to the specs that you see listed in your owners manual. It is a little bit of science and art and frustration to tame a VFO. Oddly using the same ceramic tank coil former, same tank coil wire, same mfg air variable capacitor, same PC board traces etc. you would think there wouldn't be very much change from board to board that would necessitate using so many different values and types of Temp Coefficient capacitors.

Also, have to remember the VFO in these radios was designed to support SSB and CW modes and not the modern so called digital modes that perhaps would be more sensitive to frequency change.

Nothing wrong with adding a Huff-n-Puff after you have done the normal cleaning of the rotor wiper contacts, the 9vdc trimmer pot, the RIT trimmer pot, solvent cleaning of the PC board, and a good visual inspection as you have found out. I have had pretty good luck taming them in customers radios doing the above and have never had to resort to trying different temp coefficient capacitors or installing a Huff N Puff.

If you are old enough will remember the old days with our boat anchor transmitters and receivers when we had to try different TC caps, add damp chase resistors or heating strips to the VFO case or radio chassis, leave VFO tube filaments on all the time, dedicate an individual filament transformer to the 1st Oscillator tube etc. Not only did we not really know what frequency we were on within about 5khz we had to chase each other up and down during a QSO. I had a friend whose call letters were "DMO" and we called him "Dont Move Over"!

Kevin,
So we don't have to look through the parts list, what rig is this for?
It is not uncommon for the tuning slug to bottom out...and refuse to come up to the top..there is the; heat the slug with soldering iron..and try and turn it;...a small drop of super glue on the end of a tuning wand..and try and get it out;...or unsolder the "can" and access the tuning slug from the bottom of the "can." The latter works the best if the slot on the top part is cracked...you can swap end for end as each end has a slot.
Or, try Bob Mansker ke4ftf "at" mail "dot" com. He may have one

Topic: 51674 Message: 51674

This question is about a TS-180s, which of course isn't a hybrid, but I'm wondering whether it might also come up with some of the hybrids.

A Kenwood bulletin suggests reducing drift by change and relocating a capacitor. It is no longer available but they have a substitute, but the substitute is on indefinite backorder. Does anyone know what the characteristics might and and how I might find an alternative?

Capacitor 18Pf 50V Ts180 881FF12UJ8K857 (from the parts order)

To me, the primary differences are the WARC bands and the adjustable filtering. I would not say the 830 is “better” – but it really depends on your intended application.

If you are a 75m rag chew & net guy, then 820 does everything you want. On the other hand, if you want to chase CW DX on 30m, then the 830s is the rig you need.

Both are excellent! Sweet sounding and classic.

Topic: 51653 Message: 51677

Bob

Easy to tell which board you have. If you have the -14 series look down in the gap between the tank cap and the tank coil and you will see it. If you have an -04 series little harder to see as it is printed under the shaft of the tank cap and the large brass colored anti-backlash gears.

As to schematics it is all over the place. Depends on if you look at owners operating manual or service manuals and what year. Kens K4EAA large schematic shows the -04 board with the outboard C14. It is probably the most common schematic. Operating instruction manual 15207 B50-2738-00 shows the -14 board with C14 on the pc board.

With the -14 board C14 was moved from its location off the PC board to on the board. You can see it in parallel with TC-1 trimmer and C13 22pf.

Unfortunately KW didnt do a very good job of ensuring that the documentation aligns with the model year and the as-built configuration. If you look at 1981 and 1983 service manuals you will see schematics that show C14 off the PC board. To best of my knowledge the VFOs in those years were -14 series boards and not -04 boards. So C14 should be depicted on the board.

Additional complication is you cant go by what is installed in your TS530 or TS830 as very easy to swap them around. You can today buy a 1 million series 530 or 830 off Ebay and it will come with the -14 series VFO installed which of course it should have the -04 series installed.

In the long run it really makes little difference which board you have as both have close to same temperature stability. In theory you would want to have the later -14 board.

I have no thermal chamber or themoelectric modules so I cant do any scientific VFO stability testing to compare them. Best I can do is run on the bench with regulated 9vdc and monitor output on good warmed up frequency counter. Can use canned air or a soda straw and breath or some prefer to use tip of soldering iron and direct air stream or heat at each TC caps one at a time and watch if any of them cause the frequency to take off. If they do then they are defective and can change that one cap out and repeat as necessary (Hard to find NPO and N caps in required values today. May find COGs in the values you need).

As I mentioned in my first post need to try the items I list there first to correct excessive drift before you get into changing suspect TC caps. Of course if jumping or cutting in and out that has nothing to do with TC cap.

Kevin,
You do not have to remove the RF board...unless you want to.
Remove the screws holding the AF/AVR board in place...and gently fold it over to expose the cover plate under the RF board. Remove the screws holding the cover plate in place..and the foil side of the RF board is right there. If you do not have one already..get a good, clear copy of the Service Manual and look at the X-ray view. The 7Mhz "can" can be unsoldered from the foil side and removed. Be careful with the heat..you don't want to lift a foil pad/trace. Look at the bottom of the "can" and you should see that is open and using the appropriate tool...NO METAL! turn the slug. Usually after I totally remove the slug, I use a small piece of waxed dental floss between the slug and coil form. This takes up some slop..and the wax acts as a lube...

A good clear copy of the Service Manual can be had from: n6wk "dot" com and w5rkl "dot" com

Terry,
Thank you for the excellent treatise on the VFO board variations. I'd like to post that info in the files section with your permission. The Yahoo search is not so good for these kinds of things.

Maybe coincidental, but the foil side on the board has J25-2765-14 on it. I have found some NPO SMT caps that I could use. But since it seems to be working well, I will probably leave it as is. I may try experimenting with the other VFO to see how it reacts to the NPO's minus the stabilizer. - Bob W8RMV

Bob

In old days we all played with taming drifting VFOs especially if home brewed.

Heath Co use to supply you with handful of NPOs and N750s etc for some of their transmitters like the DX-100 and Apache free of charge if you contacted them and told them you had excessive drift. You would remove the original mica caps and install the TC caps. They would also sometimes recommend a different tube for the commonly used 6AU6 tube.

Much easier to try different TC caps in most of the old boat anchor tube VFOs because they used point to point wiring and not a pc board. So you could make multiple capacitor change outs on a phenolic terminal strip with no fear of lifting a PC pad or trace trying different caps.

Point is that it is not easy to do much VFO taming on the KW VFOs as you may have to do multiple unsolder and resolder for a given capacitor. Best thing to do is try to find the bad TC cap using method I described and just change it out with same value and same TC and do that just one time due to risk of damage and not easy to remove the VFO pc board to access the foil side. Going back with same capacitance value and same TC assumes that KW did a decent job of stabilization on the assembly line.

Now that you have the Huff n Puff working I would not mess with trying to stabilize it by changing TC caps and be careful if you venture down that path on another KW hybrid VFO. It might be cheaper approach in the long run to install a Huff n Puff board. You might want to try the Cumbria X-lock the next time.

51685. Installing sacrificial .82 ohm resistor -NO!

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-03-28 20:44:00 UTC
From: wagstw46@...
Topic: 51685 Message: 51685

Just listening on the Kenwood Hybrid net on 40 meters and a fellow checked in and advised that he found the small L1 series plate choke blown open in his KW hybrid. He has replaced it with the 0.82 ohm resistor used as a sacrificial glitch resistor in the Drake L4B linear amps HV supply lead. He highly recommends that other hybrid owner should follow his lead if they experience a failed L1 choke. He stated this mod will protect and save the final tubes. I was unable to throw the BS flag as I have lost one end of my 40 meter antenna and waiting for it to warm up to put it back up.

In short DO NOT perform this mod.

This fellow is probably well intentioned, but he is apparently not versed in grid driven tetrode vacuum tube fundamentals. You cannot compare the design of a PA stage with a Triode tube in grounded grid config like the L4B with a grid driven tetrode amplifier like we have in our Hybrids. Two very different animals.

Nothing wrong with placing a sacrificial element in the plate supply lead of a grounded grid triode tube amplifier to protect in the event of tube arc over, but NEVER NEVER want to open the plate voltage in a grid driven tetrode. If you do that the Screen Grids of the 6146 finals will remain energized and act as the Plate and will pull heavy screen grid current and exceed the 3 watts screen grid dissipation and destroy your 6146 final tubes.

His advise is flawed on two fronts.
1. First as mentioned you never want to have the 6146 screen grids energized without 900vdc HV supplied to the anodes of the tubes. Very easy to exceed screen grid dissipation and quickly destroy the finals.
2. Secondly, there is a reason why KW engineers installed L1 choke and was not as a "fuse". It is there because it is very difficult to wind a solenoid choke that will provide high enough inductive reactance from 1.9 mhz to 30 mhz without having at least one series resonance hole fall close to one of the ham bands. Usually between 21 and 24 mhz. It is not a simple matter of just winding more wire on the main plate choke to provide the additional needed reactance for 160 meter operation. That could be done if the additional turns could be space wound on the form. This is precluded as it would make the chokes ceramic former too tall for the PA cage. So the next best approach is to add the additional winding needed for 160 meters operation by installing a smaller micro-henry value choke at the base of the main plate choke at a right angle to it. It is placed at a right angle to reduce any mutual coupling.

So in summary L1 is there for a reason. You can buy a replacement L1 from Ken K4EAA or perhaps from RF Parts or even Mouser. Again DO NOT install any kind of sacrificial glitch resistor or fuse in the anode lead at any location. You can install a non-sacrificial glitch resistor to limit fault current during a tube arc over event, but make sure you use a heavy enough pulse rated resistor that will not blow open and will limit the fault current until the main transformer primary fuse blows. When that happens the anode voltage and screen grid voltage to the 6146 finals will both be opened.

As with all recommended mods for our KW hybrids make sure they make sense technically before you charge off to install them. Many are ill conceived and this one is about as bad as it gets.

Realy going have to investigate my latest TS 820. Somebody has done some type of mod, the carrier control is now a power control. If I adjust the control it's turning the power down and when meter is meant to read the ALC setting there's mothing. Modulation is still in the scale and mic gain still works fine. I can see this on my external power meter.
I wish people would leave these lovely radios alone. If they want to modify something BUILD WHAT THEY WANT!!!

Mark:

I have a OCF dipole up with feed point at 45 feet on tower and short leg to my home roof and the long leg goes to big tree and the end in the tree came down. I had a pulley and counter weight to address the swaying in the wind. Not sure why it broke. Have to climb the tree to examine and repair and getting too old for that!

Yes I was screaming "No No No" at the rig and almost called your cell so you could correct him.

All is well and very busy here. Seeing lots of 820s and 830s these days as well as trying to answer emails. Little time to improve or add Hybrid info to my website. I did just add a paper on how to troubleshoot TS530 receiver SSB audio distortion in response to off list email. I need to work on one on troubleshooting transmit audio distortion, but slow going.

Suppose to be in the 50s next week so maybe I can get antenna back up.

I kind of hope this fellow is a member and sees my admonishment and puts his Hybrid back to stock config. I hate to see him loose his 6146 finals. I wonder if he lost his L1 at same time he lost his cathode resistors? L1 never intended to be a "fuse".

Take Care

Ed,
Ken-k4eaa is still selling parts. If you want the replacement lamps, just place your order via his web site. His xyl Barb, usually takes care of the orders...and usually parts are on the way(if using PayPal..etc) in less than 24 hours via USPS Priority mail.
I made a recent purchase of lamps, and the RL-1 replacement from Ken about 2 weeks ago...the items were in my mail box in about 3 days.
There is another source of parts..from a member of this group...hybridrestore "dot" com

Kevin,
Glad you got it to work. The procedure I told you about is really not that hard. THE most difficult part is identifying the part that needs the work. Some of those boards are very crowded...and even using the Xray view, it can be a bit of a challenge finding it/them on the foil side.

51694. HYBRID NET UPDATE (March 29, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-03-29 21:29:56 UTC
From: Mark Gilger
Topic: 51694 Message: 51694

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by Jimmy,
WB2KNR. There were 22 stations checking in under good band conditions.

We had the following number of radios checking in.

5 running TS-520(x)
2 running TS-530(x)
6 running TS-820(x)
5 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

Jimmy was running the net with his TS-520 and SB200 amplifier.

The Sunday net was run by me, WB0IQK. There were
7 stations checking in under fair band
conditions. We had the following number of radios checking in.

3 running TS-520(x)
1 running TS-530(x)
0 running TS-820(x)
1 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-940S + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome

as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total = 142, Sunday☐s total = 88
December 2014, Saturday☐s net total = 92, Sunday☐s total = 86
January 2015, Saturday☐s net total = 110, Sunday☐s total = 84
February 2015, Saturday☐s net total = 103, Sunday☐s total = 98
March 2015, Saturday☐s net total =80, Sunday☐s total = 51 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

51695. Nearly deaf TS-820S by 30 db

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-03-30 04:36:00 UTC
From: Jeff AC0C
Topic: 51695 Message: 51695

I've had a TS-820S for a couple of years. Fixed the display and let it sit on the shelf. Now I'm ready to put it back into active service. But it's clearly got a "hearing" problem.

A quick check shows that the required signal to hear a signal over the rig's internal noise level is about -90 dBm. That's 30 db or so below what I think it should be. The loss of sensitivity is the same across all bands.

Before I put it on the bench and start stepping through the front end, I am wondering if there is a common failure mode that matches up with this description?

1. RF-1 and 9vdc proper level? 2. What is common ahead of the Coil Pack board?
A. Bad solder connection at Ant lead wire at SO-239 center pin inside PA cage and/or loose locknut?
B. Bad Ant TR relay contacts?
C. Bad Xverter Switch contacts?
D. Bad RF Attenuator Switch contacts? Can rule out A to D if Marker signal is also down.
3. Bad L8 Ant Step Xfmr on Coil Pack board? Rare to have bad L24/L25 wave traps. Rare to have bad Q2 RF amp. L8 is a little tougher than L41 but nearby lightning or accidental transmit RF can take it out.
4. Bad/Dirty Molex Connectors?
5. Since low on all bands rules out bandswitch contacts.

May not be in the front end. Could be RIF issue on IF board. You apparently have good RF sig gen so pretty easy to find via signal injection method.

Quickly determine if in front end or IF by injecting 8.830mhz @ -53dBM (500uv) into RIF at RF-1 Pin 1 molex connector on RF board. Assuming S-meter is calibrated reasonably close this should result in approx S9 indication.

From: David Boothe
Topic: 51695 Message: 51698

Jeff,

Terry sent a great checklist for a starter but I wanted to pass along that I had a similar problem with my 820S after some work which required loosening the RF board and unhooking the Molex connectors at the top. After re-assembly, the receiver was quite deaf (not totally) and even the marker signal was very low. Seemed like the AGC was kicking in excessively after switching to receive.

Turned out it was the Molex connectors on the top of the board. I took them off, put them back on and jiggled them and problem solved. Also re-cleaned the contacts before putting the lid back on. No recurrence. Sometimes these old connectors don't like to be disturbed.

This check is on the K9TW list.

Dave

I always remove every TS820 RF board for two reasons. 1. To have good access to the VFO shaft wiper
2. To check and often replace the Screen Grid divider resistors that have gone high or open.

When I do that I always Deoxit all 6 molex connectors on the RF board and the Coil pack board. These are the connectors I was refering too in the off air RF signal path.

Sadly the problem is more and more due to bad crimps on the ends of the lead wires to these molex connectors or the spring metal tapered or wedge shaped contact has broken off the tip of the crimp connector inside the molex connector body and is just floating inside that space.

Sometimes you can find the open or intermittent one by gently tugging on the lead wires with needle nose. To check the tapered or wedge contact have to use sharp tip tool like soldering aid and release the lock on the crimp terminal and pull it from the connector body.

If it is a bad crimp I am seeing more and more people pull the lead wire and abandon that portion of the molex connector and cut off the bad crimped terminal and skin back to bare conductor and solder directly to the board.

I dont like that as have to unsolder to remove the board. Risk of lifting a trace on these old phenolic boards.

When I find this condition I splice on a short known good stub end and heat shrink it and re-insert in the molex connector. I can do that as I have several donor rigs to harvest wire harness leads from.

You can buy wire harness pieces from Bob Mansker if you want to avoid soldering molex lead wires directly to your pc boards.

I tried to do a little research to see if I could find the exact crimp on terminals and didnt come up with anything. Maybe could take a photo and send to Molex to see if they still make these terminals. Then you could crimp and solder on a new terminal as usually is enough lead wire to pull up and re-terminate.

Thanks for the comments Terry. I will let the board know how it turns out.

I also picked up a 830S that has been collecting dust and has quite a number of problems – most of which seem to be related to sitting unused and age. No end of projects queued here!

Subject: Re: [TS-520_820_530_830] Nearly deaf TS-820S by 30 db

If it is a bad crimp I am seeing more and more people pull the lead wire and abandon that portion of the molex connector and cut off the bad crimped terminal and skin back to bare conductor and solder directly to the board.

I dont like that as have to unsolder to remove the board. Risk of lifting a trace on these old phenolic boards.

When I find this condition I splice on a short known good stub end and heat shrink it and re-insert in the molex connector. I can do that as I have several donor rigs to harvest wire harness leads from.

You can buy wire harness pieces from Bob Mansker if you want to avoid soldering molex lead wires directly to your pc boards.

I tried to do a little research to see if I could find the exact crimp on terminals and didnt come up with anything. Maybe could take a photo and send to Molex to see if they still make these terminals. Then you could crimp and solder on a new terminal as usually is enough lead wire to pull up and re-terminate.

Terry, you are the magic man. It took longer to pop the case top than to find that the first molex pin set nearest the front of the rig was the culprit. Back in action and plenty of sensitivity. My XG4 at –107 dbm was reading S4 on most bands – and surprisingly S5 on 10m. Had a long Q with a fellow in OK tonight and the rig was fine. Thanks again!

Yes that is RF-1 connector and 1st pin is your 8.830 mhz RIF signal from Q6/Q7 mixer output. Always best when easiest fix cures the problem. Much better than a bad L8 Ant step up transformer!

I think you mean XG-3 or perhaps a typo. Off top of my head S4 to S5 is about right for a -107dBm (1.0uv) signal at the SO-239.

I bought an XG-3 and I carry it to hamfest as signal source for testing. Very handy for that. To make it more versatile for a bench RF sig gen really need to marry it up with a good step attenuator. For example to cal the S-meter you need to be able to input 0dB or -113dBm to adjust T6 on IF board for AGC threshold.

Hello All,
I'm looking for the .047uf Mica Caps for the Final Board for a TS530S. One blew it's top several weeks ago when the finals went. Since then, got it working again with so so finals I had around and put a lower voltage rated cap in the burnt ones place. Also did the protection mod, but I'm hesitant to put my new finals in until I get the cap replaced. Any good low cost sources?

Hi Ashok,

Sorry he wouldn't provide that information but I can understand why he keeps it confidential. I might suggest contacting Kenwood and see if they have the engineering data for the transformer but failing that, I would think any good transformer rewinder could disassemble yours and get the data they need.

Wish I could be more help.

I have never seen the VA rating of any of the KW hybrid transformers. Any time I call Kenwood (California) their standard answer is KW hybrids are no longer supported and no design data is available, but worth a try.

Pretty easy to use a wire micrometer and measure the diameter of the conductors used in each primary and secondary winding to determine the magnet wire gauge.

Also can weigh the transformer which will give you a rough estimate of the VA rating. Rough rules of thumb include:
1. 1 pound / 10 watts
2. 1 square inch of core area = approx 30 VA.
3. (5.58 x Core Area) Squared = VA

Of course have to convert the units to metric for rewind in India.

Will also have to pay attention to the special center tapped windings for the DC to DC converter.

Lastly, make sure you tell the rewind shop that the voltages listed at the secondary windings are "names" of the various supplies and not the actual secondary voltages. For example the "800" winding is not 800vac. It is approx 335vac to feed the voltage doubler. 335 x 2.828 = 947 vdc no load. The "14" winding is approx 16 -17 vac. Will be somewhat variable depending on the value of the AC line voltage provided to the transformer primary.

What you really need is someone with a spare good TS520 transformer to energize it and provide you with the no load open circuit ac voltages for each winding. I suspect that your primary voltage will also be different than stateside. Perhaps 220 or 240 @ 50hz ? Would be good if one of our members across the pond that has same power grid could provide you with all the no load voltages.

I dont know if the shipping cost would be prohibitive, but Bob Mansker KE5FTF@mail.com has good pulled original TS520 and TS520S transformers in stock and his prices are very reasonable. Probably would have to pay for Bob to construct a plywood shipping crate and not sure if he would do that. Drop him an email.

This is the best I can do.

They are disc ceramics and not mica.

Mouser among other suppliers carry them as well as may find them on Ebay.

These are CK caps which means not Type 1 TC caps. These are Class 2 caps used for bypassing and decoupling. Something like a X7R would work. Very easy to find.

As to voltage 500wvdc would be overkill, but fine for this application. I dont know what original wvdc rating is but suspect 100 volts.

Since there are multiple bypass caps in parallel while you have the board folded over I would replace all of them at both tubes as all may have been stressed with 900 vdc from the anode to the cathode. No need to use a combination of different capacitance values. Just go back with KW installed config.

I wrote Bob and he should get in contact with you. With two failures now it really compounds problem for rewinding it. No way to know if the shop should rewind it now based on present as found winding turns and wire gauge. Always best to do a post mortem on the original failure to try to understand why it failed. We have no way to know if that was done just as we have no way to know if it was rewound to spec. It is not common for these transformers to fail.

If you have to rewind it make sure to use a shop that can dip and bake using a thermal set resin. Dont brush or spray the resin on the windings. Idea of dip and bake if done correctly is it fills all the voids and it will really tighten up the windings. Dont want any vibration because of the noise and it may cause the winding to rub and cut into the E I lamination stack and eventually fail again. Of course today VPI would be even better but not necessary and small shops wont have that capability.

Hopefully shipping wont be too cost prohibitive.The best option would be to get a good used pull if you can.

Good Luck
Terry K9TW

Topic: 51719 Message: 51719

Hi Group,

I have a Ts-520SE with an odd audio issue. The received audio is "quiet" and sounds distorted (starts to crack) if I turn the volume up past 3 or 4 on the AF gain control. This happens in all modes. It's usable as it is (I can hear stations just fine), but it's quite annoying when trying to pick out weak signals. Comparing to other 520's it's definitely a problem.

I noticed that I have the same issue with the sidetone audio, so I'm focusing around the AF board audio amps. I measured Q3 and Q4 on the AF unit while receiving, and Q3 reads 13.3v, 14.7v, 12.7v (BCE). Q4 reads 11.93v, 0v, and 12.58v. (BCE).

I don't have reference voltages to compare to, and I'm still learning how to troubleshoot this stuff. Can anyone offer some direction on where to begin looking? I have tightened the AF unit screws and 'toothpicked around the board with no changes.

Appreciate any help,

-Tyler

Measure the resistance of Q4 case to chassis ground. Should be same as if measuring the meter leads shorted together. If much higher than that try gently snugging up on the heat sink mounting hardware.

Thanks Terry. Measuring the case of Q4 to ground measures 1.5 ohms or so, about the same as shorted together. Measuring the case of Q3 to ground starts around 38 ohms and climbs up to ~59.

Topic: 51719 Message: 51725

OK it appears then that Q4 collector is grounded, however my DMM lead resistance is much lower around 0.06 ohms and that is what I would read from Q4 collector to ground. If your lead resistance is 1.5 ohms and you are reading Q4 case to ground as 1.5 ohms then it looks like the hardware is making good low resistance connection for the Collector. Q3 reading is good as well. That is same resistance reading you should get if you read the 14vdc post on the AVR board to ground.

Sometimes the heat sink hardware gets loose. Usually that causes intermittent output and not distorted output but it was worth a look.

With 14 vdc supply to the board and both Q3/Q4 turned on you should see approx 7 volts at junction of R11/R12 swamping resistors. If the Emitter voltages that you report are accurate then it appears that Q3/Q4 are barely turned on.

Q2 serves dual purpose of signal voltage gain and current source for bias diode D5. I dont remember how hard it is to get BCE readings on Q2? I seem to recall you can get to the leads from component side. I like to use flower arrangement pins with some insulating sleeving slipped over them. Can get at craft stores. Usually come with a pearl ball on top to help grasp them. I connect the pin to meter leads with mini-grabber test lead and can then prod down into the board thru holes at the devices. Kenwood component density and mounting the devices with very short leads didnt make it easy for us to get any active device voltage or signal measurements from the top side of the boards.

One thing you could do from component side of board is check D5 diode. You should be able to get on it with and use the diode check function of your DMM. You should see R8 470 ohm resistor close to it. One end of R8 is the anode of D5 and you can get directly on the cathode lead of D5. Measure and then reverse your meter leads. Should read infinite in one direction and about 0.50 vdc the other direction if the diode isnt shorted. Do this check with the radio turned off.

Thanks for the help Terry!

R11/12 appear to be cased in something (it's two white blocks between Q3/4). Would it help if I flipped the board over and took a measurement at the junction, or was that just an observation?

I checked D5 as you suggested (in circuit). My diode test function did not "beep" like it normally does, but came back with a reading of 0.958. I flipped the leads and it read "open". I noticed the cathode of D5 was touching a capacitor next to it, so I gently pried it off and took the measurement again and got the same reading.

I was able to get a reading on Q2 - it is 0.8v, 11.87v, 1.48v (ECB if I'm reading it right). I'm just using an old Fluke77 meter to get the readings.

No trying to avoid flipping the board over.

How did you measure voltage at the emitters of Q3/Q4? They will be very close to same voltage as the junction of the two swamping resistors. Should be able to prod at the thru hole of C7 and measure the emitter voltage. If C7 was shorted you would have nearly 13vdc on emitters of Q3/Q4. I am not an audio guy but I belief that C7 is what they call the bootstrap capacitor and if it were shorted or leaky it could change the bias at Q2 base.

Are you placing Fluke lead at the end of 470 ohm R8 that is closest to D5 diode body? It should not take 1 volt to turn it on. I would think around .5vdc.

It is typical for diode to go open or shorted and not some intermediate condition.

I hate to have you pull the board but that is what it will take to lift one side of D5 to test and/or replace and to test and/or replace C7 electrolytic. If you do fold board over probably good idea to replace D5 and C7 but that is easter egging and I hate to do that.

Dont do that until I think about this some more or someone else jumps in to help. I see that the schematic calls D5 out as a V06B and that is a common 100piv silicon power diode. Nothing special about it. It clearly should not have a .9vdc barrier? Can replace it with a 1N4002 or 1N4007.

Jimmy Lamanteer WB2KNR is now specializing in the repair of TS520 rigs. Suggest you write him and ask him what he would do if this radio was on his bench. Sometimes easier to just swap boards than to shoot trouble to the component level. Might also write Bob Mansker to get idea of what he gets for a good Audio board.

With an O-scope and audio gen could see where the distortion first originates. Absent audio gen could use the side tone signal as it is a pretty clean sine wave.

Lastly have you listened with headphones or plugged in an external speaker? If clean in the headphones then could simply have a bad speaker.

Thanks again for the help.

I measured Q3/Q4 emitters by just putting the probe on each leg of the transistor. I will check it at C7 too.

I did have the probe on the leg of R8 closest to D5. Actually, before I read your note fully I had already flipped the board and measured on the bottom, and got the same results. I understand that this would be an atypical failure if the reading is right, perhaps the battery in my meter is low? I'll replace it and measure again just to see.

I may have parts on hand to replace D5 and C7, and I don't mind swapping them out. Do you think it's worth a shot? I also have a meter that measures capacitance and can check C7 once it's out.

I emailed Bob Mansker about the cost of just replacing the board, if that's affordable I'll take that route. I do have a scope, and that's a great idea using the sidetone signal to trace. The audio is low/distorted even with headphones and external speaker.

Sorry about that.

I got confused about Q3/Q4 package thinking same as the TS520 and TS520S. Forgot that the SE uses the TO-220 package and easy to take CBE readings.

Hi Terry,

The 520SE service manual does not have the board layouts, and unfortunately the label for this capacitor is UNDER the cap so I can't see it to be certain, but I believe this to be C7 (see red arrow). I'm assuming that C8 is the one to the left between the two transistors.

If this is in fact C7, then it's the wrong size. The schematics show it should be 100uf, but it's actually 220uf. Could that be a problem? Sorry if I'm jumping the gun, or possibly looking at the wrong thing, but thought I'd mention it. The only 100uf capacitor I could find on this board is on the top right of the picture (definitely not C7).

73,

-Tyler

You should be able to use the TS520S xray views and the cap that you have indicated in Red appears to be C7 to me.

Would you please repeat the CBE readings on Q3/Q4 with the Side Tone Oscillator keyed and the AF gain at comfortable listening level perhaps around 9:00. Make sure you are on B and E leads.

I checked out the 520S xray views and agree that it's probably C7 and that it's 220uf instead of 100uf. I haven't touched it yet, though. I should note, that C8 is a black electrolytic, while the others are all blue, so it's possible someone has been in here before and maybe put the incorrect capacitor on C7? Just a guess.

I remeasured Q3 and Q4 with sidetone ON and AF gain at 9 oclock (roughly 2.5 on the dial).

Q3 BCE = 13.18v, 14.55v, 12.55v
Q4 BCE = 11.85v, 0v, 12.53v

I wasn't sure if you meant also measure B->E, but I went ahead and did that too. Q3 read 0.629v and Q4 read 0.692v B->E.

These are the right transistors, Q3 is labeled 1061 and Q4 is A671.

73,

Well according to the SE schematic C7 should be a 100uf and not a 220uf. If possible I would look at C8 to see if it is a 100uf and not 220uf. Perhaps during assembly the two caps were reverse stuffed?

As I stated previously I am not an audio amp guy and you wont find very many receivers that use a BJT Push Pull OTL stage and not much design info in the audio amp texts that I have seen. What I do know is that if all is well you should see approx 1/2 of Vcc at the Emitters of Q3/Q4. So if your 14 vdc supply to the board is 14.55vdc then you should see approx 7.28 vdc at the emitters and you are seeing significantly more than that. Only two components that look suspect to me are C7 and D5. D5 based on your testing that revealed 0.9vdc barrier.

So at this point unless someone else has a better idea only thing I can suggest is that you pull and test both C7 and D5 and you might as well change them out at that point.

I think you said you had an O-scope. If so connect it to SP out wire wrap terminal and key the sidetone or turn on the Marker and adjust the VFO (marker may give slightly cleaner sine wave output) and observe the output signal to see if what you are hearing is cross over distortion. You should see a nice clean sine wave with no flat area or steps at the zero crossing point.

Another thing to look at that isnt involved with CBE readings not looking correct, but can cause noise is if your 14vdc supply is not clean. You can look at it with your O scope as well and should see very low mv ripple on it. On the order of 5mv or so.

That's a good idea to try.
My TS900 has a push-pull audio amp too and audio was sounding terrible. So using my O-Scope, I connected the probe leads to the audio dummy load that was plugged into the external speaker jack, and I could see a lopsided sine wave (with the marker signal on). The 900 has a current measurement adjustment on the audio board that is covered in the service manual's bench alignments. But instead of adjusting it to a specific current measurement using a multi-meter, I adjusted it to make a nice sine wave on the O-scope, and my 900's audio is so wonderful now. That simple adjustment made a big difference in the audio and I guess it to be a current balance circuit for the two transistors running in a push-pull configuration.

Hi Jan:

I have never seen a TS-900 and of course the TS520 series audio output stage has no trim pot in series with its compensating diode. And no way to open the collector circuit to measure current. So not possible to adjust the idle current or Q-point which is what it looks like they would be doing by adjusting this trim pot. It would be great if we could assure that both output transistors conduct the very moment that their respective sine wave half cycles begin.

I suppose we could measure the IR drop across the ballast resistors and compute the idle current but I dont know what I would do with that info.

I am suspecting that the compensating diode is the culprit here but not certain.

Might be fun to watch the output on Scope and bring solder iron tip close to the diode and see what happens.

In the past I have tried to do some study on Class AB push pull audio amps employing BJTs, but never found any circuits that exactly matched what KW designed for the TS520 series and I just learned from you that they also installed in the TS900 rigs. Actually to my ear I like the sound of this config better than the IC output devices in the later Hybrids.

Have a great Easter.

Hi Gang,

Well, the mystery continues! I removed D5 and C7. C7 was 220uf, and I'm not even quite sure what D5 is. Out of circuit it measures "open" in one direction and "1.10" in the other...

I replaced D5 with an IN4002, and C7 with the appropriate 100uf capacitor. I fired it up, and it sounds quite a bit worse now (overdriven and a slight 'buzz').

Here's a picture of the old D5 -- 2015-04-04_1325 - Tyler81's library
http://screencast.com/t/rHpfWPFW5ibq

Here's a short clip of how it sounds now. Prior to this, it was quite usable (just very annoying) -- https://www.youtube.com/watch?v=hRM5qAGtmpA
https://www.youtube.com/watch?v=hRM5qAGtmpA

Bob Mansker has a replacement board available. I'd like to fix this board if possible, but if it makes more sense to just replace the board I can certainly understand that.

73, thanks again for everyones help!

Tyler

I have to apologize to you. I have been working off the TS520S schematic and I should no better as there are changes on the TS20SE that KW did not publish just as there are from the TS520 to the TS520S models. I have bum doped you.

What keyed me to this is the green/black color on the pulled D5 body. I have seen this before I realized it was not a standard power diode.

Your D5 is not a silicon power diode. It is what is called a Stabistor. It is used for bias stabilization and it does consist of two barrier junctions in one package. It will read from 1.1 to 1.4vdc forward voltage. You cannot replace it with a single 1N4007 or any single silicon power diode. You can place two silicon power diodes in series to replace it.

By installing the single diode you have gone the wrong way on bias current for your two output devices thus the additional distortion.

I see that they also use a 47 ohm current limiting resistor for R38 instead of a 12 ohm resistor.

If you have enough lead length you might be able to cut the diode lead from the cathode end and tack another one in series with it. Just have to observe the correct polarity.

Again I apologize for this. No point in me measuring D5 in my TS520.

Hi folks,

after long years as a SWL I decided to join the ham-ranks and managed to master the examination for the german class A. My first contact to ham radio was more than 30 years ago at DL0XK, the Universität Kaiserslautern club station. They had (and have!) an TS820 as RF transceiver. After doing lots of reading in the internet I decided to go for a hybrid Kenwood instead of a more modern rig and found a complete TS830-line (TS-830, SP-230, AT-230, MC-50 and VFO-240) for a reasonable price.

I intend to use this rig mostly for SSB and PSK31. I know that the TS-830 has about 100W output at SSB. However, SSB has a lower duty cycle than the continous output of PSK31. I will have to reduce output power for PSK31 to lower the stress on the power tubes. How do I manage this? Tune the rig normally and lower the output by reducing the NF level of the sound card? Somewhere I read about using a variable voltage at the ALC input to reduce output power, is this the way it is done for PSK31 (or any other operating mode with 100% duty cycle)?

No problem at all, Terry. Since it's still measuring good I'll just put it back. I took care when removing it. I should have mentioned that it didn't look like a regular diode.

Knowing C7 was the incorrect type I'll examine the other components to see if something else was installed improperly too.

I wouldnt put it back. At 1.1 vdc it appears to not have high enough forward voltage. MV-13 means 1.3 vdc.

You might be able to put it back and reduce the value of R38 to get the bias current where you need it at.

I would try to run the board with it folded over with jumper test leads making up the board ground planes to the chassis ground. This way you could try different values of R38.

I think I would first try two and three 1N4002 diodes in series before putting original D5 back in the circuit.

Ahh, understood. Does it matter if the forward voltage exceeds 1.3v? With two 4001's in series it's a little under 1.1v, with three in series it's a little over 1.5v. I assume this would be ok?

Terry,
Yes, I went back to my 900 S/M and says exactly like you said, to set the operating point (idle current measurement). And I compared the 900 & 520 AF board circuits and are basically the same configuration. Now, my 900 pot that I adjusted is VR2 (100 ohm) and is equivalent to R38 (47 ohms) in the 520. The 900 adjustment would be the same as the measurement of current from the 520's Q4's collector to ground. They say it should be 50ma.

Jan:

Well in theory should only have to be adjusted only once for the characteristics of the factory installed complementary transistor pair. In theory the devices shouldnt change with age. However we do see "leaky" transistors. Of course a pot is more expensive to install than a fixed resistor especially if going to be set once and never touched again. Suspect that is why dont see pots in the 520 series.

If either of the pair failed down the road and had to install a replacement device (and most likely have to use a sub) then it sure would be nice to have the trimmer pot so can set the Q-point for the new transistor (s). Absent that would have to depend on the value of R38 and not easy to try different values.

These things are so frustrating trying to trouble shoot long distance. In matter of minutes by looking at the audio waveform at Speaker or across 8 ohm dummy load can usually tell what is going on.

Got to go watch my grand daughter look for her Easter baskets! Enjoy your Easter.

Tyler

It wont destroy anything, but it may not correct the distortion.

We know if you go with 0.5vdc forward voltage diode the bias current wasnt correct and made the distortion far worse. So my thought was since you had the board folded over why not temporarily try 3 diodes in series. Make a long loop and tack solder in the place of D5 and then if no improvement could short one diode for 2 in series. Problem with using 1, 2 or 3 diodes is it doesnt give you any fine adjustment of bias current as a trimmer pot would.

Lastly you replaced or checked C7 and found it wasnt shorted or leaky so it cant be the reason for high voltage at emitters of the output devices. Perhaps it is not a bias issue. Maybe Q3 is the culprit. It appears to be near saturation if you read high 13vdc at its emitter. So instead of being biased to that point maybe it is shorted?

I am just guessing now as I am not able to witness the CBE voltages and/or look at output with O-scope so probably doing you more harm than good with my responses.

I need to back away and let someone with more push pull audio amp experience help you.

If you decide to buy a good pulled AF board from Bob Mansker and want to sell your bad AF board I would consider buying it from you as a parts board. We can discuss that off line if you are interested.

51751. TS-520S - Removing mods & SSB Output Issue

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-04-05 09:05:17 UTC
From: christopherlarwood@...
Topic: 51751 Message: 51751

My Easter project has been examining a TS-520S I've had some time and about time I made some progress in getting it fully operational.

The radio was purchased through ebay and the seller was economical with the truth in describing the radio and accessories. However RX is good, CW output and power is good also. There is a problem with SSB output.

But firstly, at some point in history, someone decided to do a few mods. Firstly, the RF Volt control pot on the side panel as been replaced with another pot which seems to act as a squelch!

A pot has been fitted to the rear panel. It is connected in series with a .470k ohm resistor to the RF unit near D17 & seems to be have replaced R68. It should be a 10k resistor. I don't know what function it serves?

A two position switch has also been fitted to the rear panel. There are two connection wires from the switch running to what I take to be filter electrolytic capacitors (?) - shown on P13 of service manual Bottom view C15, 16. A 3rd connection from the switch runs to what I take to be a ground terminal on the tranverter on-off switch. I'm guessing this is power output mod. Unless anyone can advise otherwise, I expect simply unsoldering the connections and removing the switch is the best course of action.

While CW tunes up to 100 watts or so, SSB output is non existent unless the mic gain is tuned way up and speech processor is on. Without the processor there is little output. The mic is a MC-50 and works perfectly. This points towards mic amp problem on the generator board - going from the troubleshooting guide.
What are the first things to check? There are no obviously faulty components. Any guidance appreciated.

Nice write up and pics. Thanks for sharing

I'm having low SSB output problems with my 520S. Good on CW 100w out but without mic gain wound flat out and processor on, little audio on SSB. A different issue to yours

Christopher:

I think you are correct that this mod is to defeat the ALC action or to introduce different level of ALC action in SSB mode.

Q10 ALC Amp is configured as a "dynamic" zener diode. R68 10k resistor sees current in SSB mode when you over modulate and cause positive grid current to flow from the 6146 final tube control grids thru the FG lead and back to the -C supply. That current thru R68 is varying at an audio rate. It causes up to a negative 1 volt to be produced at the Collector of Q10 (-1.0vdc). So in effect it becomes a variable low voltage negative power supply that is placed in series with the ALC bus supply. (you may refer to it as rail)

The ALC bus voltage at the Collector of Q10 is normally set by RF-1 to be approx positive 3.2vdc (+3.2vdc). The ALC bus voltage is a dc control or servo voltage for Gate 2 of Q1 TIF amp on the IF board. Some call it bias and that is not correct. Q1 produces the RF drive that is applied at input of the Transmit Mixer on the RF board.

When you run mic gain so that there is 6146 positive grid current (on voice peaks way outside of the black printed scale) Q10 ALC amp produces up to -1.0vdc which then bucks the +3.2 vdc ALC voltage and results in approx 2.2vdc control voltage available for Gate 2 of Q1 TIF amp. This reduces the RF drive level to the TX Mixer and ultimately to the control grids of the 6146 final tubes. It ensures that you dont over drive the finals and produce adjacent frequency splatter on the bands. For ALC to work you have to let the horse get a little way out of the barn door before you slam it shut on him! This mod is leaving the door wide open!
What this mod appears to do is defeat the ALC action or allow you to control the amount of ALC action in SSB mode. Some people play around with the ALC RC time constant components to keep the ALC bus voltage up between words and syllables to get some level of compression. I have never seen it done like this.

I would remove it and place Q10 circuit back exactly as you see it on the schematic.

The ALC bus should have no effect on your receiver or act like a squelch in Rx mode unless they are also running wires to the AGC control voltage to the IF board and also bucking the 3.2 vdc to the gain controlled stages (IF amps and RF amp). I have no idea why they would want to do that. If anything they would want to run RF-1 higher than approx 3.2vdc which is not good idea as it would effect signal to noise ratio. No point in running RF-1 much above 4 volts at Gate 2 of the devices as reaching knee of the curve and diminishing gain increase beyond that point.

What you can do before removing it is connect your VTVM to the AGC bus on the IF board. Your meter impedance will cause the 3.2 AGC bus voltage to pull down to approx 2.6vdc and drive the S meter up scale. Assuming you have RF-1 set for approx 3.2 vdc should see something close to 2.6vdc with your voltmeter connected . Now adjust that trim pot that use to be the RF sens pot and see if your AGC bus voltage varies. If it does then for some reason they are also messing with the AGC bus with this mod.

Part of problem with ill conceived and poorly executed mods is the challenge of discovery. Almost never know if you have found and removed everything that has been done.

As to mic input could have bad solder connection at the mic jack on front panel. Best to use audio generator and inject along the entire path. If suspect mic connector can inject at phone patch in. Can also inject at BM terminal and work whichever direction is indicated. Usually not too hard to troubleshoot. If no audio gen then any device capable of audio output. Tape recorder, Lap top sound card, music player etc.

51755. Hybrid Net Update (April 5, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-04-05 21:01:48 UTC
From: Mark Gilger
Topic: 51755 Message: 51755

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by Mark,
WB0IQK. There were 21 stations checking in under good band conditions.

We had the following number of radios checking in.

4 running TS-520(x)
2 running TS-530(x)
7 running TS-820(x)
3 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-830 + Drake L-4B amplifier.

The Sunday net was run by me, WB0IQK. There were
9 stations checking in under fair band
conditions. We had the following number of radios checking in.

4 running TS-520(x)
2 running TS-530(x)
1 running TS-820(x)
0 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-940S + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome

as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total = 142, Sunday☐s total = 88
December 2014, Saturday☐s net total = 92, Sunday☐s total = 86
January 2015, Saturday☐s net total = 110, Sunday☐s total = 84
February 2015, Saturday☐s net total = 103, Sunday☐s total = 98
March 2015, Saturday☐s net total =80, Sunday☐s total = 51
April 2015, Saturday☐s net total = 21, Sunday☐s total = 9 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

From: tfrugia@...
Topic: 51719 Message: 51756

Hi Terry,

I tried 3 4002's in series and it lowered the emitter voltage to around 12v. Audio sounded much better than with the single 4002, but still not quite right. I assume with a pot and 2 4002's in series I could get the bias to the right level.

I think at this point I'll just buy the replacement board and swap them out. I'm having fun troubleshooting this but with my limited knowledge we may end up flooding the group for months on something that might be completely obvious if you had the board in front of you :)

I appreciate all of your effort in helping me. Once I get the new board I'll update this post :) I'll contact you off-list about the board.

Best 73,

-Tyler

Got my latest TS 520S back from a mate that got it going (he knows heaps more than me) and I was testing it on a dummy load and external power meter and after a few minutes it stopped trans. I checked the bias and it peaked to 70ma then faded to nothing, now there's no bias ma at all. On RF the radio meter still reads out put but nothing on the external, with no bias I shut it down to prevent further damage. There was no smoke, it just stopped transmitting.
I run my radios at 50ma but this one shows nothing. Any advise were to look will be a great help.

There are two ways to approach this problem - the "shotgun" method of the "systematic" approach. Let's try simpler shotgun ideas first to eliminate some of the simpler items.

Cycle the screen voltage switch on the rear of the rig, making sure it lands on the "ON" position.

Remove and clean the internal contacts of the relays.

OK, now a more systematic approach:

What can cause a loss of plate current?:
1. PLate voltage is low or non-existent. Measure and repair.
2. Screen voltage is very low or nonexistent. Measure it. There are resistors in the screen circuit that often open up. They are associated with the "TUNE" control. difficult to find on the schematic, but they are there.
3. Cathode resistors have opened. check the resistance (power off !)
4. Bias voltage is very high, forcing the finals into cut-off. Measure it and repair.
5. Your meter is non-functional which could be the relay contacts.
6. Bad finals? doubtful, but possible. They would have to be shorted or DEAD to not have ANY plate current.

This is a partial list.

since the plate current is not present at idle transmit, its not a drive problem. Its in the final circuit or the power to the final circuit, somewhere. Since you say the meter shows some output, but the external power meter does not, hints to a relay problem. very common in these rigs after sitting idle for some time.

Good luck, Careful of the voltages!!!

Hi Neil and Tim,

Non-existent 6146 plate voltage can result in permanent damage to the 6146 screens. Lack of 6146 plate voltage will result in the 6146 screens becoming the plate which results in excessive screen current permanently damaging the 6146s, hence no IP current.

Tim, are you referring to the HV Unit R5 and R6 resistors? If so, they typically don't cause loss of IP current but rather cause a higher reduction in screen voltage to the 6146s causing loss of ALC during TUNE mode only. Failed R5 and R6 on the HV Unit will have no affect on the 6146 screen voltage in CW, USB, and LSB modes.

The 100 ohm final unit/final amplifier screen resistor typically don't fail.

A failure in the 210A Rectifier Unit supply can cause the same symptoms even with the SG switch set to ON. This will affect all modes. A check of the 6146 screen voltage can be done by connecting your DC volt meter to pin 3 on the 6146 tube socket with the SG switch in the ON position. The voltage should be approximately +255VDC. Change the SG switch to OFF, pin 3 voltage should change to approximately minus 105VDC or so. This will tell you if the 210A supply, the -C bias supply, and the SG switch are all working as they should.

Bad cathode resistors will also cause the same symptoms. Check the cathode resistance from pin 1 on the 6146 tube socket to chassis, it should be something close to 5 ohms. If the resistance is infinity then the cathode resistors are open which will result in zero IP current indication in transmit. The ALC, IP, REL PWR, and HV meter settings only work in transmit.

Relay RL1-3 terminals control the switching (varying) of the bias voltage applied to the 6146 grids when switching from receive to transmit. If relay terminals RL1-3 are bad, it can keep the 6146 bias voltage at or closer to receive levels. The bias voltage levels on pin 5 of the 6146 tubes in receive is approximately minus 101VDC or so. Switching to transmit, the bias voltage level changes to approximately minus 65VDC. Connect your DC volt meter between pin 5 and note the voltage. Next, key the transmitter in sideband, MIC control set fully CCW, and note the bias voltage level. They should be close similar to the levels stated earlier. If they are not, meaning the bias voltage remains at or close to the receive levels whether in receive or transmit then check RL1 first. I have a pdf file on my website that shows the energized and non-energized terminal connections. The BLACK arrows shows the non-energized connections while the RED arrows show the energized

connections. The view is from the bottom of the relay. The numbers were taken directly from the bottom of the relay, they are small and for those who have eye sight problems like me, a magnifying glass will help to see the numbers.

If the meter works on HV with the transmitter keyed then the meter relay, RL2-2 is working. Relay terminals RL2-2 is a simple SPDT switch, switching the meter to display AGC variations (S meter) only in receive and ALC, IP, REL PWR, and HV in transmit. Not much to that switch that can go wrong. RL2 is located below the chassis next to the final amplifier and rear panel and RL1 is located below the Marker and VOX Unit board, top left rear.

The 6146s filaments are wired in "series" with 12VAC applied to pin 2 of the front 6146. Pin 7 of the front 6146 will have 6.3VAC that's also applied to pin 2 of the rear 6146 through a jumper wire. Pin 7 on the rear 6146 provides the ground to the chassis to complete the filament circuit. If one 6146 filament is open, it doesn't matter which one, then both 6146 filaments will be dark resulting in same symptom even if the heater switch is ON. The first 520 in the 520 series has point to point wiring in the final amplifier. The 520S and 520SE have a PC board in the final amplifier. The PC board foil runs replace the point to point wiring.

Topic: 51765 Message: 51765

Hi guys!I've made a mistake and my TS-830s is in trouble.Shallow or deep, you tell me.I tune and load at 14.2 Megs as usual and using my manual ATU I tried to find a good match of my antenna.I wasn't keying continuously but the breaks were short. Then I hear the noise. A kind of hissing noise and and a flicker of the meter lamp. I switch it off immediately and I used my ear and my nose to hear and smell the trouble. No noise but there was smell of magic smoke.I took the covers of and I tried to see a blackened component or something. I couldn't, so I took the plunge and switch it on again.I still can tune and load, only this time when I load the needle on mA indication pegs out of scale. If I reduce carrier on CW I can keep it quite low. When I am using SSB I have power but the mAmps are excessive. I reduce the load so I can see the needle into scale, I dip the mA and then loading again it goes out of scale.Definitely I need your help!I am full of ears, my multimeter is on and my iron is hot. 73

Takis

With limited information, you need to check the 20 ohm resistor resistors on the final board, there are 4 from memory which have a total Resistance of 5ohms. You can discharge hv supply then remove front tube and using torch can look at board throught tube hole st resistors

Tskis,

You must change all 4, as they have have all been stressed. When you have the board out you should check disc caps as well, be careful not to cover heat tracks when changing resistors.

Mike,
I have tried to reply twice now and it doesn't get into the conversation. Probably a problem with my computer.

Nice idea about the filament. Hadn't thought about that.

I disagree about the screen voltage problem. With no screen voltage, I have seen zero plate current on a tetrode. And I have seen 520's with open screen resistors.

True, if plate voltage is gone, and screen voltage is present, the tube could be damaged.

I think Neil has a good list of items to check.

If I had to guess, I suspect the relay first, given his description in the original post.

Cheers,
Tim

Hi Tim,

Don't know why you had problems posting a response, maybe Yahoo was having problems.

Anyway, I didn't say the screen resistors never fail, I simply said they typically don't fail. I probably should have included a statement that says there may be times when they do fail.

Very rare for a "grid stopper" to fail ie go open on any of the KW Hybrids. If you find open Stopper then you are going to be tossing a final tube in the trash.
Far more common to drift somewhat high in value which is no big deal. I have a white paper on my website about purpose and replacing these resistors.

Screen grid dissipation is only about 3 watts so easy to destroy the tube long before would ever burn open a 100 ohm 1/2 watt carbon resistor. Put a 1/2 watt resistor on the bench and power it to dissipate 3 watts and see how long it can cook.

Now R6 470 ohm CRC Pi filter resistor on the HV rect board does darken and burn up more commonly and may open interupting SG 210A supply. The root cause of that is more likely to be bad input filter cap than a shorted screen grid within the tube. Also, when R6 burns up it can result in a carbon track on the rect board below R6.

This is why Ken K4EAA supplies a new R6 in his resistor kits.

Another reason R6 may be burned is bad Driver Tube screen grid divider resistors on the RF board. Very common on the 520 and 820 series.

There is an interesting clue here. If what he reports is accurate that he has meter indication in the RF relative power position in Tune or CW position when trying to load and no IP indication then he has to have 6146 final tube cathode emission.

There simply isnt enough Driver feed thru power capable to provide sufficient RF voltage at output of the pi-network for any RF indication even with the RF sens pot cranked full. That tells us it is metering issue. Either needs to pull and clean the Aux Control relay contacts and/or clean the meter selector switch contacts.

Also, if what he reports is true that he has RF relative power indicated and no RF output on an external wattmeter he needs to pull Ant TR relay and clean its contacts and/or check his coax jumpers to his wattmeter and dummy load.

Lastly, where in the owners instruction manual does it tell him to set the zero signal plate current to 50ma and what does he think he is accomplishing by doing that? A subject for another day.

My 20 cents worth.

Terry K9TW

My newly aquired TS-830 shows low power output into a dummy load. The wattmeter at the AT-230 shows about 70W CW-output at 40m or 20m after tuning. I have a 1:10 divider at my dummy load, so I put a scope to it. It shows an perfect sine at about 10Vss after the divider. This computes to about 25Weff real output.... not quite what I was expecting.

I'm reading lots of blog posts and of course K4EAA's excellent "Mailbag" postings about this, so I'm concentrating on the usual suspects... kathode and screen resistors and the 6.8uH rf choke. The previous owner told me they used the rig as a club station receiver and someone managed to smoke the kathode resistors previously... I ordered the replacement parts from Ken, we'll see how this will change things.

Thanks to everybody for the responses. Every thing has been taken on board and gives me heaps to ckeck. The 50ma came from a post on this group from a restorer that said 60ma is only maximum and he sets all his to 50. As for the relays, I do have 2 new ones that will be tried along with known tubes. What I'm getting is no bias amps when function on IP and keying on L/U SSB but on CW with ALC or RF settings the meter on the radio does read 3/4 scale but my Heathkit HM 102 External meter reads no output. It was working fine on the dummy load then just stopped transmitting. Doing some tests the bias reading spiked to 70ma then the neddle faded down to nothing. The tubes are glowing so I know the heater's working. IT WONT BEAT ME
Once again thanks heaps for all the advise and places to look

Hi Neil,

I think you need to get the voltmeter out and
measure a few things - specifically the voltages
at the tube sockets. Write them all down and
check against the service manual and/or report
back here. These measurements should give you a
clue to your next step. I'm not sure I'd be
changing tubes until I had a sound reason to do so.

Of course we should always remember that high voltage kills, be careful.

As an aside, why do you adjust your bias current
to 50mA and why did you chose that value?

Topic: 51758 Message: 51778

Neil:

Where in the operating manuals to you read that 60ma is the maximum or approximate resting plate current and OK to set to 50ma?

The TS520 and TS820 manuals even use the words to adjust " for a correct 60ma". What it does say is if the plate current is higher than 60ma when you key the transmitter not to leave it keyed more than a few seconds. This is concern about the effects of long key down time in the off resonance state and nothing to do with setting the zero signal plate current to the design level.

I dont know who the "Restorer" is that you are quoting. All I can tell you is there are restorers and then there are restorers. Lots of folks clean and lube and call that rebuilding or restoring. Lots of beliefs, folklore, and opinions abound. If you dont understand the technical basis for why you are making an adjustment you need to get more than one opinion. Even that may not always help you as from time to time the consensus of the group or common practice can be not the best practice or flat wrong.

You say your rigs "dont mind" running at 50ma idling current. Not sure how you measure that they dont? Also, that is taking a very narrow view. The question should be is what is it doing to your Spectral Content of your RF output? Which way does 3rd and 5th order products go as you lower the idling current? You need a spectrum analyzer and understand 2-tone testing methods to evaluate IMD.

Your Hybrids PAs are designed and configured as Class AB1 grid driven SSB LINEAR amplifiers. The choice of the bias point by the KW design engineers for SSB service was an important one and not an arbitrary one. Admittedly it does require a compromise between zero signal plate dissipation and low intermodulation distortion (IMD).

The problem is that design engineers are paid to care about IMD and the effects on the bands, but operators in our new "me me" world not so much anymore. If you dont believe that just spend some time on the bands. Misadjusted transmitters coupled with no understanding of the bandwidth of a properly adjusted and operated SSB transmitter has become very common place. Frankly it is inconsiderate, rude, and just might involve the terms of the license.

For transmitting tubes most manufacturers provide plots of IMD and PEP output power as a function of zero-signal plate current. For a given Screen grid voltage and Plate load there is ONE value of the zero signal or static plate current which will provide minimum distortion. The goal is have the most linear portion of the load line curve to intersect with the zero signal plate current line.

As I mentioned there is a challenge for the designers and they do have to compromise between tube plate dissipation and IMD. There is a rough rule of thumb and that is that setting the zero signal plate current for the minimum IMD will result in approx 2/3 of the tubes rated plate dissipation. I will leave the exercise of calculating that from a 6146B 35 watt dissipation rating for you. I can tell you that lowering the resting plate current from the ideal location does result in IMD increase. The dB amount of that increase is of

course dependent on how far you move away from the Class AB1 bias point.

Lastly, setting your "resting plate" current to either 60ma or 50ma will have absolutely NO measurable impact on the tubes operating life span if that is what you and the "Restorer" are trying to accomplish here and I suspect that is the case. Long off resonance key down time, loading for "max smoke", loading into opens, operating high duty cycle modes like RTTY without reducing plate current are some of the things that can and do shorten your 6146B or S2001A tube life. Also, long key down times can also hurt the 12BY7A driver tube that is biased for Class A.

By the way lots of terms are used:
1. Idling current
2. Resting plate current
3. Static current
4. Quiescent current
5. Q-point
6. Zero signal plate current

I like number 6.

Neil I am not trying to pick on you. However, when you come on a technical forum and participate in what should be a thinking mans game and make a pronouncement of how you adjust your transmitter you have to be prepared to explain why you are doing that. I submit that you would be better served to always error on the side of the KW engineers until the test of time proves otherwise. The way that should happen is through a factory developed, authorized and distributed service bulletin. Also because Heathkit or some other 6146 SSB transmitter manufacturer sets the resting plate current to 50ma means nothing. At minimum you have to look at the operating screen grid voltage and plate voltage of their design.

In the end the rigs are yours and you can run them anyway you want.

Hi Neil,

I wasn't having a crack at you when I asked the
question but as Terry said the bias setting is
specified by the manufacturer for a particular
class of operation (AB1) of the amplifier in your radio.

Our hobby is technical in nature and we generally
make measurements with a high degree of accuracy
and designs are generally of high detail. Terry
has demonstrated in a clear technical detailed
fashion why a Kenwood Hybrid should be biased at
60mA, perhaps you could ask the restorer to give
his reasoning technical why it should be set at
50mA. Terry doesn't need my help but I agree with him.

Regards

Lou
VK3ALB

P.S. How is the radio going, have you made those measurements yet?

Hi Lou:

Of course most important thing is for him to get his radio repaired and back on the air. Plenty of help here to assist with that.

I am sure that at the moment 50ma vs 60ma is least of his worries, but it didnt look like anyone else was going to ask Neil why and hard for me to sit silent. I dont expect him to blindly accept what I provided. I would hope he would go back to his source and ask the Why question.

Hardest thing of all is trying to understand the problem statement as written and if you can accept it to be factual. When these forums have real time video like Skype feature it will be a great help.

If at the present time he has RF relative power indication and no Ip and no RFoutput power indication on an external wattmeter it sure sounds like multiple problems to me. Pretty hard to have RF relative power indication with no 6146 cathode emission. Maybe get him to carefully measure keydown Cathode voltage?

Appreciate your support.

Mike,

Some confusion may be caused by different rigs using different idle plate current set up with the same RF setup (12BY7A driver and 6146B finals). The Yaesu FT-901DM is set to 50 ma, but this is no doubt due to the different plate and screen voltages this rig has compared to the KW hybrids, and to preserve AB1 linearity at those settings, as Terry explains.

Hi Neil,

I wasn't having a crack at you when I asked the question but as Terry said the bias setting is specified by the manufacturer for a particular class of operation (AB1) of the amplifier in your radio.

Our hobby is technical in nature and we generally make measurements with a high degree of accuracy and designs are generally of high detail. Terry has demonstrated in a clear technical detailed fashion why a Kenwood Hybrid should be biased at 60mA, perhaps you could ask the restorer to give his reasoning technical why it should be set at 50mA. Terry doesn't need my help but I agree with him.

I have done some further investigation as to the "squelch" control which has replaced the RF Volt adjustment pot.

A small separate board has been fitted, mounted about the AF unit on the underside of the radio.

It has 4 connections going from it to the AF board and a 5th (purple) connection which connects to the bottom side of the IF board via a diode.

Do I just unsolder and remove as it only seems to serve as a squelch unit?

I recently purchased a TS-520S, with matching speaker, VFO, Digital Display and Mic. It also came with a transmatch. All are kenwood, except for the TXRX, its a TRIO. I bought it from the original owner, Who had bought the radio just before joining the Navy, used it for a few months, and never got an other chance to use it.

Im planning on using this rig due to its legendary status. Should I stop now, and just recap the the whole rig, or should I try the old Variac method for its first start up? Im a heathkit guy, and this is my first Trio-Kenwood.

Thanks a ton,

> or should I try the old Variac method for its first start up?

Carefully clean the switches and controls first, there are a myriad descriptions in the group archives of using DeOxit or some other brand cleaning solution to do this.

THEN use the Variac and slide your way up to full voltage. You may be surprised to find that you needn't change any caps or other components. Or maybe not, but you will have given it a chance before diving in with a soldering iron.

The problems encountered with long-term storage of these beasts seems to mainly revolve around oxide corrosion of the switches, the band switch wafers in particular. Small amounts of contact cleaner, working the switch through its range of motion, repeat a time or two, and then blow off the residue with 'canned air' or a filtered high-pressure air supply (if your bench or shop runs to such).

Inspection of the innards for obvious things like cracked resistors or broken diodes. (I had three diodes on the rectifier board with cracks all the way through them, in my 520SE.) The caps were all fine, despite several years of being stashed in a closet.

Why has MY original post, atleast I think it was MY POST, gone from a radio with NO BIAS to how much I run on the others. I appreciate all the advise given and when I get back to my weekender I can take some readings. But I wont do it without my mate present since he's better at the technical stuff. I can do some of the tests but when it comes to high voltage better safe than sorry. He's the brains I'm the muscle still learning. I saw the post about 50ma when the person was telling a new comer here about the 50ma and I replied it should be 60 as per the book and he said with the age of the radios how can we be sure our meters are accurate. I wont give his name as I wont point fingers but if you want to know go back about 6 months to previous posts.
All I want to do is get the old girl going again NOT cause arguments.

GM John and I'm soooo jealous!
I'd suggest pulling the covers and inspecting the innards of each box. If all looks okay then definitely use a Variac to gradually power up the units individually. K4EAA is a great source for parts for these rigs and has a web site. I'll bet the rig will come to life just fine. I've powered up several of the same vintage and had wonderful results.

I powered up the radio, the VFO light wouldnt light up, but I was getting some static. I was connected to a Dummy Load. I checked the VFO-520, It was fine, it was the Interconnect cable... it had a few issues. After fixing that, The VFO light lit up, as would the RIT light, and the Fix light. The Meter lights don't light up, but the Dial lights do, but dimmly.

Following the VFO calibration, I set the switches correctly, put the TS-520S VFO switch to CAL-RMT, I was able to beat the frequencies, then all audio stopped. No more 0 beat, no more static. So, I will have to chase that one down for sure tonight I think.

Also, is the Drive knob usualy fairly stiff to move? I looked inside, and everything is still all nicely oil/greased, and clean. I mean... It moves smoothly, just with some resistance.

PLEASE remember to properly sign your posts. tnx n 73 Joe wb7uqu

Gday,

Got tuning up radio. Refer yo manual for peaking, dipping and peaking sequence. Once tuned for cw output only, turn car control anti clockwise. Thidveill sllow carrier output to be controlled. There I'd s small 9v circuit that can be made to control alc rail to lower output power. Look in file section of this forum

The Kenwood hybrid QRP circuit can be downloaded from my website.

www.w5rkl.com

Click on Manuals and Documents link at the top of the page. When the page comes up click on #24 under Kenwood Manuals and Documents. The file will download, free, to your computer and automatically open Adobe Reader to allow you to read the file.

A DIN Plug will be required to connect the simple DC circuit to the TS-830's rear panel REMOTE DIN socket pin 6 and ground. Tune up is normal by following the instructions in the operator's manual. Once tune up is complete, switch to sideband (USB or LSB) and adjust the QRP circuit pot for the desired RF output. The QRP circuit can be built on a simple Radio Shack perf board and housed inside one of the plastic cabinets along with the 9 volt battery.

It's not possible to "preset" power output using the CAR control when tuning the transmitter. The CAR control is used only in TUNE and CW modes, it's disabled in sideband. Adjust the MIC gain for normal output then adjust the QRP circuit for the desired reduction in RF output level in USB or LSB. Do not use the QRP circuit in CW mode, use the CAR control to control power output level in CW mode.

If you are reducing power for psk operation you don't need the QRP circuit!

You adjust the transceiver's MIC gain for normal voice sideband
operation and leave it alone. You do not touch the MIC gain when
switching from normal voice sideband to PSK operation. You adjust the
PSK transmit tone levels on the sound card interface or the computer's
volume control for a power output between 20 and 30 watts.

Thanks Mike. This is all part of my learning experience. In reading about adjusting the power level I saw the difference in the TS830 between SSB CW mode controls of power but have more to learn.

I also checked the schematic for the remote connector to follow pin 6 to an RAL signal on the circuit board. I haven't found the list of abbreviations yet to understand the connection between RAL and the ALC control. I also learned that the DIN plug used by Kenwood would change a switch in the chassis Din mating connector. Based on what I have read I assume that does not affect the external ALC control circuit.

Thanks for assisting a newbie

Topic: 51806 Message: 51806

Hi to the group !
I have a AT-200 that I am trying to repair. It's nothing big just a simple part but no clue where to locate a replacement. The part is the wood/fiberglass shaft/coupler that connects the R-TUNE knob to the tuning variable. I have not been able to find a parts list for tuner to be specific about the part needed. Again it's the shaft that is like bamboo or fiberglass. Any help would be greatly appreciated. ...Thanks in advance Jose N1USB

All Kenwood parts - even for a new rig such as the 590SG - are sold through PacParts, not Kenwood per se.

http://www.pacparts.com/

However, I would seriously consider the brass coupler from Ken K4EAA. If you own a Kenwood hybrid, you will come to appreciate his website, and what he offers.

Hi Roger
You are correct the plastic or nylon shafts do have a
little pin through them you have to remove the pin
to remove the shaft from the variable capacitors
if it were to fall out of place the tuning knobs would not turn the variables caps.
Still looking for nylon shafts
Thanks all for your help Clint

I have my 599 twins working and check into the 40M Hybrid net yesterday.
One detriment thing I noticed is the lack of BCB rejection on 80M and I
found even on 40M. I going to try using an inline high pass filter.
I see Clifton Labs makes them, for the RX only. This will work with the
R599:
http://www.cliftonlaboratories.com/z10020_am_medium_wave_band_reject_filter.htm
and this one can stay in-line between the Xcvr and Amp.
http://dlwc.com/
That might be the way to go.

http://www.dxing.com/tnotes/tnote06.pdf http://www.dxing.com/tnotes/tnote06.pdf

If it is just a particular AM broadcast station that causes your problem a "suck out trap" is very effective way to go. A 1/4 wave coax open stub will look like a series resonant circuit (low Z) and shunt offending signal to ground. Easy and cheap thing to try as a first step.

Can make a 1/4 stub trap by calculating the length of coax needed, install at Coax Tee connector at the receiver SO-239, connect the coax stub to the open Tee and coil it up and place on floor below the operating position. For example if the offending AM station on 80 meters is at 3.35mhz the calc is as follows:

492 (for 1/2 wavelength) X velocity factor of the coax. (can use cheap RG-6 TV coax). From coax tables use .81 VF. Then 492 x .81 = 398.52 ft. 398.52 ft/2 = 199.26ft / 3.35mhz = 59.48 feet. So cut off 60 feet of RG-6 coax, install a PL-259 connector on one end, leave the other end open, coil it up (18 to 24 inch coil) and ty-wrap or tape it. Lay on floor under the operating desk. You can cut it a little long and prune it little at time to raise the null frequency.

Takes some experience to know how much to trim. Of course if trim too much you are starting over so dont get too greedy! Better way is to adjust the length using a Grid Dip Meter or should be able to use one of the modern antenna analyzers to find the Zero impedance point. I have no experience with any of them.

The Joe Carr Tech Note discusses Wave Traps and BCB filters and shows a filter design that is very similar to the AM BCB filter in the TS-830 front end ahead of Q1 RF amp.

If you like to homebrew and there is room in the 599 could build this adsorptive BCB filter or just copy the TS830 BCB filter design. A BCB filter of course wont help you with the 3.35mhz station as in my example.

You can see a sweep of the TS830 BCB filter on my website.

Remember that the 1/4 wave stub filter will also have very low impedance at 3/4, 5/4, and 7/4 and shunt any signals at those frequencies to ground. 3 x 3.35 = 10.05 mhz , 5 x 3.35 = 16.75 mhz and 7 x 3.35 = 23.45mhz. So you have to see if you can live with the trap effect on these multiples for a given offending station.

Date: 2015-04-12 23:35:10 UTC
From: Mark Gilger
Topic: 51817 Message: 51817

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by Jimmy,
WB2KNR. There were 19 stations checking in under poor band conditions.

We had the following number of radios checking in.

3 running TS-520(x)
2 running TS-530(x)
2 running TS-820(x)
3 running TS-830S
0 running TS-510
0 running TS-511
2 running 599 twins
0 running TS-900

Jimmy was running his TS-520 + Drake L-4B amplifier.

The Sunday net was run by me, WB0IQK. There were
13 stations checking in under fair band
conditions. We had the following number of radios checking in.

2 running TS-520(x)
2 running TS-530(x)
1 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
1 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-940S + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome

as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total = 142, Sunday☐s total = 88
December 2014, Saturday☐s net total = 92, Sunday☐s total = 86
January 2015, Saturday☐s net total = 110, Sunday☐s total = 84
February 2015, Saturday☐s net total = 103, Sunday☐s total = 98
March 2015, Saturday☐s net total =80, Sunday☐s total = 51
April 2015, Saturday☐s net total = 40, Sunday☐s total = 20 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Iv set the radio up again, to do some further testing. Im Glad Iv got some matching Kenwood Headphones, as the audio comes from the headphones, but not the built in speaker. Tomorrow I will further test using the SP-520 external speaker. I think that the internal speaker just may have never been put to use at all.

Im also going to be swapping the Meter and Dial Lights out for some LED's to make it nice and bright. Im going to match the VFO lights as well. After this, I will focus on the rest of the receiver. I have done NOTHING with the TX side of the radio. Not even tempted to, last thing I need is to REALY blow things up. lol.

Less you could simply follow the transmitter tuning instructions in the TS-830 operator's manual starting on page 17 under paragraph 4.3 TRANSMISSION (I). There's nothing mystical about tuning the TS-830.

If you do not have the TS-830 operator's manual then you can download it on the web. I have it on my website

www.w5rkl.com

in the "Manuals and Documents" page.

Tuning the transmitter should be performed with a 50 ohm dummy load connected to the TS-830's rear antenna SO-239 socket. A ham station should have a 50 ohm dummy load and use it when tuning/testing transmitters to prevent interfering with other stations on the bands.

51823. TS-830s: what's so special about C66 (IF-Board)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-04-13 05:45:35 UTC
From: Martin Jangowski
Topic: 51823 Message: 51823

Hi folks,

I'm just doing a complete recap of my TS-830s. The caps are easily available from Farnell (except one...), and so far I have no problems replacing them. Yes, the traces on the boards are extremely easy to lift off with the soldering iron, even using a professional desoldering pump to remove the old solder and a Weller solder station with Sn60Pb40 to solder the new ones in. You have to be very careful not to overheat the traces (I can't remember seeing a non-FR4 board in a expensive piece of electronics in a long time... epoxy boards are just more forgiving.)

When ordering the caps, I saw C66 on the IF board. This is a .22myF 35V Tantal elko (located in the lower left corner of the big schematic) and not available new. I don't really understand it's function. It is involved in creating a dc voltage for a varicap at a 8.375 quartz oscillator for VBT.

My question is: old Tantal caps tend to go after several years. Why did the engineers at Trio use a Tantal cap for this? Can I safely replace it with a .22my foil cap or should I leave it alone?

Martin

Hi
Tantalum caps are generally low leakage, foil caps are not.
I would have thought that a single 0.47uF would do the job, but otherwise 2 series connected 0.47uF will be fine (providing a value of 0.235uF).

Cheers

Yes, the internal Speaker is plugged in, I checked that out. Im going to be doing some audio tracing, threw it, to see where the audio stops. Starting with the speaker of course. So far, I know the Phone Jack works, and works very well. I get good clear sound threw the vintage Kenwood Phones that came with it.

What happend with the internal speaker, was... It was working fine, then as I tried to do the TS-520S to VFO-520 calibration (Zero beat them), The speaker just gave out.. Poof, done. It may have stressed the speaker and killed it. Although that is very unusual.

Im picking up LED's and resistors to replace all of the white bulbs in both VFO's. I hope that I can find some close to the 4mm size of the current bulbs. :)

Yup, that's really what it's called. Look it up on Google. I just built one from a write up I found on the web and I have to tell you, it is amazing for tuning our beloved old hybrids (and the amplifier behind them). Using it on my 520S, I show 155 watts peak on my Autek WM1 (which was compared to two different Bird slugs) and believe it or not, 0.4 watts average! You can tune as long as you need and not hurt anything.

The write-ups on the web were all glowing and now I see why. The gentleman that used to sell it is now SK and the circuit is available out there on the web. It does use an obsolete part (74LS13N) but I found a guy that was selling 25 so I didn't bother to redesigning it into a modern part and I have plenty of spares!

If you want to reallly save those finals, have a look at it. It's really neat!

There are a number of interesting links that discuss the device. That's why I didn't reference any one in particular. The one I built it from was http://www.iol.ie/~bravo/Woodpecker.htm http://www.iol.ie/~bravo/Woodpecker.htm I did change the 82 ohm resister that drives the zener to 220 as it dropped the current to about 20ma and the output was essentually the same.

It looks to me like R81/C66 is an RC filter (snubber) for noise reduction on the DC back bias supply voltage for D24. Dont want any VBT oscillator shift when switching to TX mode. The spec is +/- 70hz regardless of the VBT pot setting.

D25 is forward biased by RLT when rig is keyed and applies back bias to D24 effectively isolating the VBT control. RLT line may not be clean and in addition to noise may exhibit an initial spike.

You wouldnt want any spike or noise on this dc back bias supply as D26 Varicap would see it. Disc ceramic cap could be used, but they can be microphonic (vibrate) and have piezo effect which Tantalums do not display.

You would just have to try a disc ceramic to see if any ill effect.

Of course you are aware not to reverse polarity the Tantalum. I have never seen a failed C66. I also hope you are paying attention not to reverse polarity electrolytics that by design have the positive terminal to the ground plane. They wont like that for very long. Must go with the as found installed config if not previously molested and not with the schematic.

Tantalum electrolytics are NOT low leakage. They are very low ESR/ESL and offer relatively high values of capacitance in small packages.

Film and foil caps are very low leakage but are bulky and can have high ESL depending on construction. They are relatively insensitive to voltage applied versus effective C whereas ceramic caps change value dramatically with static voltage.

Depending on the ceramic dielectric type chosen, capacitance can drop dramatically near full rated DC voltage. Ceramics make excellent capacitors for high frequencies whereas foil caps are not good at high frequencies, in general and depending on construction. Tantalums make good filter caps for relatively low frequencies but are problematic in that under some circumstances they will literally burn up (as in on fire). The element Ta or tantalum is rare on earth and is mostly found in some areas of politically unstable Africa and maybe Russia so the supply can sometimes get spotty.

It is far better to use something else rather than tantalum these days. Panasonic has a line of polymer caps that are well suited to switching power supplies and offer good performance as a sub for tantalums without the drawbacks of tantalum caps. I stopped designing with tantalums 25 years ago and have never found I needed them for anything that I couldn't get with alternatives.

Aluminium Polymer capacitors, Aluminium-Multilayer-Polymer capacitors in
particular, are exact replacements for Tantalum or Tantalum-Niobium units.

Aluminum we can get. Tantalum and other rare earth materials are a bit
harder to come by.

Steve (N4BOS)

I mean no disrespect but I disagree with your 155 watts output from your TS-520S.

You said:

"/*I just built one from a write up I found on the web and I have to tell you, it is amazing for tuning our beloved old hybrids (and the amplifier behind them). Using it on my 520S, I show 155 watts peak on my Autek WM1*/"

You added that you use additional "Bird" watt meters for proof of the 155 watts output even saying the differences between the different watt meters were 400mw (.4 watts).

It would be interesting to know what the TS-520S final amplifier cathode current (IP meter indication) and the final amplifier high voltage indications were with 155 watts output indicated on your watt meters?

The final amplifier in a TS-520 has a maximum percentage efficiency of 60%. The normal CW DC input power is approximate 160 watts and approximately 200 watts peak input power in sideband mode. In order for your TS-520 to produce 155 watts peak output, the input power would have to be in excess of the factory specified 200 watts and that's not possible with any of the TS-520 models. The most peak output you could expect to see would be less than 120 watts. The average power output in CW mode at the antenna connector (SO-239) would be approximately 96 watt watts (.6 x 160 = 96), transmitter tuned and tested using a 50 ohm resistive dummy load.

Again, I mean no disrespect Steve.

Topic: 51829 Message: 51841

Hi Mike,

No disrespect detected!

Let me try to address your (excellent) points. First, the comparison of the Autek WM1 to the Bird was only to indicate that both meters agreed and I used two different slugs in the Bird for the comparison. I got all the numbers I stated from the Autek after comparing the Autek to the Bird at several different CW and peak power levels and frequencies. I will not say either meter is dead accurate but simply agree with each other. I do have a peak reading board in the Bird. As for CW power out, again using the same WM1 meter, I see 100 watts plus or minus on all but 10 meters and on 10, I see a little over 90. I do not have a 10 meter antenna up (yet) so I typically run on 20, 15 and 40 using dipoles.

I perhaps didn't accurately state where the 400mW number came from... what I meant to say was that when the Autek showed the peak number, the average number on the AUTEK was 0.4 watts. I was surprised at the difference as well.

The 3898 pecker as designed in the circuit I used is stated as 10% duty cycle. The waveform is an odd one with sharp peaks both above and below DC zero but certainly not a sine wave.

I will not disagree that the 520S seems to be putting out more peak power than it should. My only point was that using the pecker and a peak reading meter results in an apparently perfect tune. I have checked it "the old way" after tuning with the pecker and it is always dead on.

I will say that when USING the radio on SSB, the same meter shows ~120-130 watts out (peak) on SSB.

Clearly the extremely short duty cycle of the pecker allows the high voltage to stay higher. Is that the difference? I don't know. All I know is that it works well, I get a very good tune on both the 520S and my SB-221 and the tubes should last much longer.

eHam has a number of glowing reviews of the device and that's why I was curious and decided to build one. So far, I'm very impressed regardless of what the REAL peak power is. Incidentally, I have considered bringing my scope into the shack and seeing what the REAL peak power is into a (decent) dummy load. I'll let you know what I find if I do that.

73,

Steve

Are you measuring the "peak" power readings while connected to an antenna? If so, those peak power values are probably not real. You have to have an SWR of 1.1 or otherwise the reflected power from the mis-matched load will upset the watt meter reading.
Try again using the dummy load on the work bench.

Hi
I am not going to get embroiled in the various capacitor technologies but suffice it to say that: applications using tantalum capacitors take advantage of their low leakage current, high capacity and long term stability and reliability. For example, they are used in sample and hold circuits which rely on low leakage current to achieve long hold duration.
I will agree that in some PSU applications, protection against the failure modes should be given. They are often still used in high-end audio applications (especially filters) due to their inherent stability with temperature and time.

I will not come back on this subject as it can go on-&-on.

Cheers
Graham

Hi,

I am in the process of restoring a TS820S . Started with frying the transformer. Had total short cuts in those large electrolytics . Got me a used working transformer and both the power and the receiver now work.
I even dared to put in final tubes and power on, with a loud bang and a flash from an resistor (R4 3.3 k) on the final board as result. Found that several components were missing on the final board . The old tubes with an unknown history may be shorted too.
My question : there are two mystery components on the final board picture, they do not exist on the wiring diagram or on the parts list.
They are R7 value 6.5 , I guess Ohms and R3 value 10 . Both are drawn as a tube like object, not like a zigzac which would be Kenwoods normal symbol for a resistor . Is this something someone on the forum has encountered . What are they, are they needed ? At least they are missing on my board . Allready received NOS tubes and have all other components in place now, but do not dare to power up before this mystery is solved.
Attached: Picture of Service Manual page with mystery components highlighted

No, the numbers were measured into a oil filled dummy load.

Let me be very clear here.... I am NOT saying the power numbers are accurate. My whole point was that the pecker appears to be an excellent aid to tuning the tube finals of a transmitter or an amplifier. The average output power is a tiny fraction of the peak output power which as to be easier on the finals.

Topic: 51845 Message: 51848

I forgot to mention very unlikely that you have a X or V model TS-820 so dont worry that your Final board does not have these two resistors.

The 6.2 ohm power resistor subs for the missing 2nd tube filament and the 3rd 10 ohm resistor results in a cathode meter shunt of 3.34 ohms instead of 5 ohms. Wont go in to the math. There are other differences as well.

This wont be the last curve ball that the TS820S service manual throws at you!

Joe and couple others on here can help you sort that out. You can also keyword search on 820 service manual and find very large number of post related to alignment questions. Not uncommon to have wrong test point, wrong adjustment component, and wrong acceptance criteria called out in a single step.

Have fun.

I am sorry forgot to comment about R4 meter multiplier resistor blowing up. I sure hope you have not lost your Meter movement. Did you also replace R2 and R3 10 ohm cathode resistors? If not you need to do that. Also I would not use the final tubes that were in the radio when you experienced the loud bang.

Some people do use the 6146 or S2001A finals over after an anode to cathode arc over event and get by with it, but I dont as I dont like risking damaging a meter that survived the 1st event.

You may want to consider installing protection mod to protect the meter in event of future arc over events. Even NOS finals that have been sitting around off gassing for many years can arc over.

So, I went threw the manual, word for word. Did all the tune up and adjustments as per. Switched to IP, hit send, BAM 600ma right on the button. Flipped to 20m... Tuned around. Landed on 14.205MHz. Tuned up on 14.200, and made a 1400km QSO on the first try! Got good reports back, and could hear his whole 950 watts. He gave me a 59 on what I imagine is 100w +- a few.

So far so good, just have to rebuild the VFO-520 inter connect cable, and make one for the external speaker. Replace the white lights with LED's and test the internal speaker for function. If all that works out.. I'm golden.

Thank you Terry , great feedback and yes I am having fun .
Did change the cathode resistors, made my life easy and used kits for capacitor and resistor replament , Hybridrestore in my case.
Meter seems to work even if the resistor R4 was charred and peeled. Is a protection mod documented somewhere on these pages? Working with the board I found the connection wires of resistor R6 but the body had been blown away , now I am unsure what caused the flashbang R4, R6 or tube.
Your warning about curve balls in documentation is well taken.
Found your detailed article on final unit protection and just got the needed components .
No 230v varistors around in Helsinki but settled for 250V dia.20mm ones. This means that there will be new undocumented “mystery components” on the board .

Looks good, I can send a picture. I replaced a few bad couplers, a few dry solder joints, it was working rx and tx, then the screen resistor blew I think it was a shorted driver tube. I replaced that and then it was dead on rx and tx. I replaced a fet and the rx came back but no tx. No more time to fool with it.

Probably be $75 to pack and ship I'll see if I can find a box but I am not sure.

Hello Group,

I normally just sit out here and read the mail, and see what I can learn, being the proud owner of a TS-520s, and matching VFO, and they do have issues from time to time.

I know sometime down the road, I need to replace a few coil slugs that are cracked, and attempt to follow the adjusting instructions, just like my bicycle endeavors I can build bikes, and wheel sets, but I have to get someone to true the wheels as I just don't do it right. So far my rig works, but I am sure it could use a tune up.

Anyway, I am scrapping out a stack of old Aerotron low band commercial radios, that are just loaded with slugs the same size as the coils in the Kenwood's, just curious if someone has tried using this type of slug to replace the broken ones.

If they are useable I should have a stack of extras to trade or sell in the future for others that have some cracked slugs as I do in my rig.

Rolf,
I am away from home right now and won't be back for a couple of days, but your picture shows the final plate choke to be a very poorly wound replacement. Also, (at least on mine) the final plate choke is NOT a simply wound choke like the 530 & 830. The 820 choke has, to the best of memory, 4 or 5 different windings...kind of like donuts on a stick. I do not know the value...but I should be able to measure one for you when I get home. I am not overly knowledgeable on this...and can not comment if one can make a new one by simple winding or does it need to be like the original.

If R6 Screen grid 100 ohm "stopper" resistor blew up then you had to have experienced a Anode to Screen Grid fault and cant imaging the 6146 Screen Grid surviving that.

Hi Craig,

Yes, I've done that. Hard to be specific but many
of these headsets have a preamp/condenser mic
insert. You can use a 9V battery to supply the
set and use a 0.1uf blocking cap on the mic line.
The specifications for your headset will tell you
what the supply voltage should be. It's generally
not too critical - somewhere between 5V & 9V. If
your headset has a dynamic insert then so much
easier as you won't need a battery. I built and
modified a W2IHY iBox
http://www.w2ihy.com/media/wysiwyg/Manuals/master-iBOX-builders-kit.pdf
in a box big enough to hold the board, battery
and power switch. Depending on your headset you
may be able to do away with the attenuator. With
the addition of a footswitch I had hands free operation!

BTW, when it comes to footswitches I steer away
from those small units that fit completely under
your foot. You're always chasing them around
under the desk. Much better to get one of those
long ones (about 29 inches long) because they
never move and are much more comfortable to use.

Regards

Lou

Rolf/Joe

Here is my data. Never validated by anyone. Rolf please compare with Joes measurements when he returns home.

The original TS820 plate choke is Pi-wound. The TS530/830 is solenoid wound. Pi-wound in an attempt to keep the series resonant holes away from the ham bands that the rig covers. Not easy to hand wind.

I have never wound a TS820 choke so cant tell you number of turns per section or the wire gauge.

DC Resistance = 2.3 ohms
Inductance = 235 to 240 uhy
Parallel Resonance (grid dip with no short across the windings) = 11.5 mhz
Series Resonant holes (grid dip with short jumper across the windings) =
1st hole @ 18mhz
2nd hole @ 42 mhz

Recognize that the TS820 did not have 18 mhz band coverage so they parked a hole there between 20 and 15 meters.

I have wound several TS530/830 chokes.
DC resistance = 7.5 ohms
Inductance = 168 uhy
Number of Turns = 205
Wire Gauge = #34
Parallel Resonance = 13.7mhz
Series Resonance holes:
1st hole @ 23mhz
2nd hole @ 33mhz

You will notice we dont care about the 2nd holes in either choke. The first hole on the TS830 choke is slipped in between 18 and 24.5 and a little too close for comfort. It is very hard to wind a solenoid wound choke to cover this big a frequency range without have series resonant hole (lower reactance) somewhere in that range.

You could email Bob Mansker at KE5FTF@mail.com to see if he has a TS820 plate choke.

If you cant find a TS820 plate choke I would not be afraid to try the TS830 choke or wind a solenoid wound choke on your ceramic former using the 830 data.

I second the idea of tracking down an original choke.

The problem with winding your own is that you cannot test out of actual installation location what the series resonances are going to be. The resonance point depends on the strays between the coil and everything around it. Which means that what you measure on the bench in isolation has little bearing on what you will see mounted in the rig.

Is it important? Yes. Just ask anyone who has encountered the “big bang” in a new homebrew amp and they will let you know first hand what happens. Having been down that road myself, building a good plate choke still falls in the realm of black magic, if you ask me.

Good luck!

Why cant you test in place? Easy to grid dip in place? Just use as loose a coupling as you can. I use Measurements 59 or Millen. Makes very little difference in the resonance points that you measure on the bench. A few khz, but certainly not mhz shifts.

As for on the bench I do mount them on a small metal pan chassis with the bypass cap attached.

I short them for the series resonance test to replicate what the choke sees in circuit. Essentially shunted by the very low Xc of the tank capacitor.

If you measure resonances of known good factory choke on the bench easy to compare your rewound one and if you use exact number of turns and wire gauge really there is no need to check the parallel or series resonant points.

When done I measure the inductance and if close to same value as the original then really no need to check the resonances. I do it just to say I did.

Wound around 6 or so of the TS530s and TS830s chokes. Solenoid wound ones are pretty simple. A little tedious for hand winding, but I now use hobby lathe. Fortunately havent seen too many burned up ones lately.

I would not attempt a litz wire or individual insulated multi-strand "basket weave" wound choke although I remember fellows back in the day made machines like the Coil Master and did wind these more complex chokes.

Terry K9TW

51865. How to spend a pleasurable hour or two while repairing your TS-830S

Hi folks,

I'm sure somewhere is written "don't allow cats into a ham shack while doing delicate work". Unfortunately, my big tom Carlo can't read (or doesn't care)...

Currently I'm reassembling the band switch of my TS-830 after unsoldering the wafers, cleaning them in the ultrasonic cleaner and resolder them. They were very dirty and oily. Now they look like new and have less than 0.05 Ohms contact resistance, no need to change anything on the riveted contacts. One small thing are the brass tubes that space the wafers and shielding plates. When disassembling the two long screws holding the wafers, one is advised to order them on a folded piece of paper to keep track of the different lengths used. Good advice... well, maybe there is better advice... string them on a piece of string or wire. I used a twice folded piece of paper, put the short brass tubes in the folds and kept this out of reach on the board behind my workbench. Exactly the place my cat Carlo used to land after jumping up the board to sit high above the serfs working with electronics....

You guessed it: After looking for several missing brass tubes on the floor (and finding several interesting and long missed things) the guesswork started. Finally, I took a caliper, measured the brass tubes and the distances of the wafers and shieldings and made a few educated guesses. It someone is interested, this is the correct sequence (all measurements in millimeters, the wafers are called W1..W7):

screw head - washer - holder - 3 - W1 - 15 - 15 - W2 - 5 - W3 - 6 - shield - 20 - 9 - W4 - 5 - W5 - 6 - shield - 4 - W6 - 5 - W7 - 5 - holder - washer - nut

Information is pouring in , thank you Joe Jeff and Terry, this is really valuable
Mine is a slow paced project, most for learning. I have never seen a working hybrid but I am trying to to construct one out of two TS 820S wrecks which looking at the amount of charred Tx components have been driven to and beyond the limit.
I realized that that my 14.60 milliHenry choke must be a replacement. I do have a second choke which comes from a second TS820S. That one looks like an improvised replacement too, has 354 milliHenry, and a 0.6 Ohm DC resistance. One of them had to be way off . Found a picture in the gallery of the “donuts on a stick” version . Could not figure out why the Kenwood engineers divided the choke in five individual coils but now got some good explanations from you. This latter choke was repositioned inside the final cage, possible to
fight the black magic of unwanted resonances, cannot ask the preowner is SK, Seems that if I want to avoid challenges and get the system running than finding the original part is the best option. Collecting information and weighing options.
I still might give it a try to wind one resembling the original myself.

73 Rolf

Dave,
Just buy the SignaLink (about $100)
http://www.tigertronics.com/slusbmain.htm
It has a 3kc audio ADC, USB plug and all the audio isolation
transformers and level controls, external speaker and so on and so on.
I used mine to do the digital stuff, very recently (last week) used it
to receive 2M SSTV pictures from the Space Station.
I never do PSK31 with the older radios, you need a later one that
doesn't drift and the clock in your computer needs to run a special
program to syncronize its internal clock. PSK31 was created for "weak"
signal operation, like on VHF/UHF/SHF/EME, but guys are using it on the
HF band, which I don't understand why. I guess its the excitement a
making a contact using just 1mW, or something.

I think there may be some comingling JT69 (weak signal, depends on time sync) and PSK31 (narrow signal, no time sync required) in this discussion. In both cases, the drift is going to be a problem. PSK31 is only about 30 hz in bandwidth so the DSP filters on the program are tight – but many programs have an AFC function which will track your signal so the other guy may be able to follow you.

The attraction of these modes especially to new hams is that it does not require much in the way of gear to be able to make Q's, and it's a lot more like a "text chat" format which a lot of especially younger folks know.

Has anyone done this, if so did you use a home brew interface or something commercial like a Signaltronics? It appears to me that you would need to connect the audio in to the MIC connector, the audio out to the speaker connector and the PTT to the auxiliary connector. That's a little kludgey but is it do-able?

Thanks for any input.

Dave

Dave,

You can either purchase a commercial pre-made sound card interface or
you can build one yourself for much less money.

The following link will show you how easy it is to make a simple sound
card interface using "VOX" to key the transmitter.

http://www.qsl.net/wm2u/interface.html

You can buy perf boards and the isolation transformers from Radio Shack
or on eBay. Cables can be those cheap audio and video cables found in
DVR/DVD players. No power is required, simply apply computer sound card
"Headphone" audio for the transmit audio and the computer's sound card
"Microphone" input for receive audio. Software is free on the web that
can be configured for "VOX" keying of the transmitter.

Dave,
You're making this WAY harder than it is.
I have an 830S and am on PSK everyday with it.

Here's what I did:

Order the Tigertronics SignaLink USB AND the Kenwood TS-830S mic cable. ~$85.
Set the SignaLink jumpers for your 830S.
Plug the SignaLink into the mic connector.
Plug the SignalLink USB cable into your computer.
Load a PSK program, I started with Digipan

THEN - you need to back off the power on the 830S for USB operation. On PSK I use 10-15W typically. To do that, I made a little voltage divider circuit that puts a adjustable negative 9v.bias on the ALC pin in the radio's Remote Connector. Got a KW cable off eBay for a few bucks to connect the circuit to radio. There are files in this group and diagrams on the web on how to make the circuit. Its just a 9v battery and a pot. Piece of cake.

These are the big chunks. I'm not a tech so if I can do this, so can you. Documentation abounds on the web.

Good Luck.
Tom

Dave,

Yes it is reasonable to build your own interface. Radio Shack website
sells the 1000 ohm CT/8 ohm audio transformers under part number 2731380
priced at 90 cents each. Dual perf boards 2760148 for $1.99 for 2.

A 1K pot to control audio levels 2710280 priced at $1.69 each, x 2 is $3.38.

Add some cheap shielded audio cables to connect the interface to your
computer and transceivers.
A simple plastic enclosure box 2701801 priced at $1.00

$0.90 (1000 ohm CT / 8 ohm audio transformer)
$1.99 (Dual small perf board)
$3.38 (2 x 1K pots at $1.69 each)
$1.00 (plastic enclosure)

$7.27

Shielded cables with 3.5mm plugs to the computer sound card would be
extra but price for cabling and plugs will be cheap. Total investment
for a simple home built sound card interface will be less than $20 and
this will give you some experience in building a simple circuit.

All parts can be obtained from Radio Shack on-line website.

Rolf/Terry,
Rolf, I can confirm part of Terry-k9tw measurements regarding the TS-820(S) final plate choke measurements:
DC resistance: 2.33 ohms...this is taking into account the meter lead resistance.
  Inductance: 241uhy
   Wire gauge is very close to 26ga(0.015 inches)...that's as close as I can get.

These measurements were taken with a spare parts coil..with nothing else attached.

I am unable to confirm the other measurements, as my dip meter is on loan to another, but I doubt that there would be a gross difference.
I am going to up-load a picture showing how the choke is wound. As I stated before, I do not have much knowledge on these items...but the suggestion of using a 530/830 choke does not sound out of bounds.

Thank you Terry for the detailed data . Studied Pi coils and got some insight. Took the advice to track down an original part and was lucky enough to find one in England which is less complicated than ordering from Bob in the US. Just orderd the choke from HifiSSB,com, hopefully it will work out. Will in between concentrate on aligning the receiver part as well as doing ESR measurements and changing still remaining older electrolytics.

I have a friend who has ordered from that Company with good success.

Yes easier than trying to wind an exact replacement. If you have means to measure inductance suggest you do so as well as give it a good eyeball. With this kind of conductor insulation not easy to have a turn to turn short. I have never seen a TS520 or TS820 Plate choke discolored. Ok to measure resistance, but really only tells you that it is not open. Turn to turn short typically wont measurably alter the total resistance.

Just as a point of interest if you want to see people winding "basket weave" or "honey comb" chokes search on You Tube and will find some home made coil winding machines that do a nice job. Some are pretty primitive made with plywood eccentric wheels and rubber band tensioners, but they work.

As I mentioned in addition to installing the correct Plate Choke I would at least replace the RF bypass capacitor as it had to be seeing more than normal RF current with these home made "chokes". Not uncommon to find it to be discolored and/or cracked and/or holes blown in it.

Have fun with your restoration project. Half the battle is "discovery". Sometimes not easy to know if you have found and undone all the hamfisted mods. Of course these attempts at RF Plate Chokes not hard to miss!

I would also suggest that you test the transmitter operation separately without the transceiver cable and receiver connected. What band are you testing on? The 3SK22 mounted in the socket that drives the 12BY7, tends to degrade from high to low frequencies (i.e. you can get drive on 80 meters but as you go higher in frequency like 15 or 10 meters, the drive drops off or is non-existent).

Topic: 51889 Message: 51889

Hi folks,

I just finished recapping my TS-830, I just feel better with fresh 105deg. electrolytics than 35yrs old 85deg. types. Reception was good when I got the TS-830, but TX power was/is low (about 25W max into dummy load with about 260mA plate current @ >800V plate voltage, measured with scope directly across the dummy load). I ordered a set of K4EAA's final repair parts (all relevant Rs and the final caps/choke). The caps in the final cage look rather well worn (blackened and pieces broken off), so I hope replacing them will restore the output power to normal values. The unit has a history of abuse (it was used in a club station with operators not very well versed in tuning a tube PA) and they had to replace the burned kathode Rs twice. I have a spare set of used RCA 6146, the current tubes are fairly new chinese products. I have lots of alc at any frequency, don't think the driver tube is bad.

I wonder if it is advisable/neccesary to try to align the unit following the service manual. Unfortunately, I don't have the complete set of test equipment available. I own a AF signal generator (old HP model) and a tube L/C RF generator, an AC mV-meter (however, with a -3db point at 1MHz...), a 100MHz frequency counter and a Tektronix 7603 scope with >=100Mhz. I don't have access to a spectrum analyser and a sweep generator (any ideas how to get one cheap?).

Martin,

In relation to the final cage damage that you are seeing, how is the choke, discoloured in any way? As you are mentioning that you have burnt\charred caps, one would have to assume that the 6.8uH choke at therear bottom of the large choke is toast aswell?? Also whilst you have covers off, have a look at the padder caps on S22 (band switch), mainly the ones closest to the first valve. Only reason I'm pointing you in this direction is because it would appear the PA has not been tuned correctly in the past and has seen some high RF power. These caps on S22 closest to first valve tend to fail and crack due to heat being emitted from value and are relevant to 160, 80 and 40m. If you find that any are cracked then must replace with type 1 RF caps, these are not easily found, and cannot be subsituted. Be interested in what you find

73s

Dave

Subject: [TS-520_820_530_830] Complete alignment/adjustment of TS-830

Hi folks,

I just finished recapping my TS-830, I just feel better with fresh 105deg. electrolytics than 35yrs old 85deg. types. Reception was good when I got the TS-830, but TX power was/is low (about 25W max into dummy load with about 260mA plate current @ >800V plate voltage, measured with scope directly across the dummy load). I ordered a set of K4EAA's final repair parts (all relevant Rs and the final caps/choke). The caps in the final cage look rather well worn (blackened and pieces broken off), so I hope replacing them will restore the output power to normal values. The unit has a history of abuse (it was used in a club station with operators not very well versed in tuning a tube PA) and they had to replace the burned kathode Rs twice. I have a spare set of used RCA 6146, the current tubes are fairly new chinese products. I have lots of alc at any frequency, don't think the driver tube is bad.

I wonder if it is advisable/neccesary to try to align the unit following the service manual. Unfortunately, I don't have the complete set of test equipment available. I own a AF signal generator (old HP model) and a tube L/C RF generator, an AC mV-meter (however, with a -3db point at 1MHz...), a 100MHz frequency counter and a Tektronix 7603 scope with >=100Mhz. I don't have access to a spectrum analyser and a sweep generator (any ideas how to get one cheap?).

51893. Hybrid Net Update (April 19, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-04-20 02:03:11 UTC
From: Mark Gilger
Topic: 51893 Message: 51893

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by Jimmy,
WB2KNR. There were 19 stations checking in under good band conditions.

We had the following number of radios checking in.

3 running TS-520(x)
0 running TS-530(x)
4 running TS-820(x)
5 running TS-830S
0 running TS-510
0 running TS-511
1 running 599 twins
0 running TS-900

Jimmy was running his TS-520 + Drake L-4B amplifier.

The Sunday net was run by me, WB0IQK. There were
7 stations checking in under good band
conditions. We had the following number of radios checking in.

2 running TS-520(x)
0 running TS-530(x)
0 running TS-820(x)
1 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-940S + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome

as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total = 142, Sunday☐s total = 88
December 2014, Saturday☐s net total = 92, Sunday☐s total = 86
January 2015, Saturday☐s net total = 110, Sunday☐s total = 84
February 2015, Saturday☐s net total = 103, Sunday☐s total = 98
March 2015, Saturday☐s net total =80, Sunday☐s total = 51
April 2015, Saturday☐s net total = 59, Sunday☐s total = 29 (Month to date)

Martin:

Given that you have no idea how many people have been under the hood, I suggest that you familiarize your self with the abbreviated alignment steps detailed in the Owners Operating Instruction Manual under Section 6 Maintenance. These are what I call the Owner/Operator alignment steps. It is essentially a coil pack alignment, abbreviated IFT alignment, and S meter cal.

The full alignment is contained in the Service Manual and is intended for Service Techs with proper test gear, knowledge, and experience level.

You may want to check Step 1 of Service Manual to set 9 vdc regulated and ALC/AGC bus reference voltage to 3.6vdc. I would also check Neutralization and Carrier null Steps 25 and 29.

As far as SSB Frequency response KW provides access holes in bottom cover to adjust TC-2/TC-3 trimmer caps. Best way to adjust is the mic line audio injection and wattmeter method to set the 3dB roll off points. Some set by ear or you can use the S-meter method that is described in the Survival Guide under Step 8.4. Lastly audio spectrum analyzer software works very well. What ever method you employ pretty easy to flip back and forth from LSB to USB and listen to the tone difference in the back ground noise. Often find one very bass and the other very treble.

Before attempting the coil pack alignment take a look at all the slug tuned cores first with a good lite to see if any are cracked. Must use proper size alignment tool for the Ant and Mixer coils and the Drive coils. If they dont turn freely better to leave alone. I have white paper on my website www.k9tw.c http://www.k9tw.conom that describes how to adjust Drive coils so they align better with the Rx peak position of the Drive control.

I agree with Jan that you should not touch the BPFs on the PLL board. You can do a rough check on the BPF alignment by placing O-scope or RF probe and VTVM on TP-3 on the RF board and measure and observe the VCO signal level and/or at the Emitter of Q35 on the PLL board.

At TP-3 should see around 1.0rms rf volts from 0 to 500 on the VFO and the display should not blank at either end of the travel.

On Emitter of Q35 will see a peak in RF voltage (150mv to 200mv) with the VFO around 200 to 250 (should be exactly at 250). The peak at Q35 is broad and better seen driving with RF sig gen in lieu of the VFO due to its tuning rate. Can look at peak with Frequency counter and scope 10X probe. Depending on the band switch position peak should occur at 14.58mhz, 24.58 mhz, or 34.58mhz.

This is rough check of the BPFs and of course much better to sweep them. On my website I have a picture of the old fashioned sweep method using RF sig gen and measuring the RF voltage at Q35 Emitter and plotting the points on graph paper. Easy way to find the BPF as found frequency response curve, but not a good way to try to make any adjustments.

So, iv been using the TS-520s for about a week now. Saturday evening while tuning up, I noticed that when I am to peak the IP using plate and load, that the meter is pegged. I had to turn the load all the way down just to bring the meter down to 2/3 scale. After that there was no adjustment below that at all. I followed the troubleshooting and lowered the RF Voltage. Now its within the range of the meter, but I can still peg the needle. This has also affected my output, now I'm only pushing about 50w at best.

Any suggestions?

John,

You said you

"Peak the IP using the PLATE and LOAD, that the meter is pegged"

If I may ask, where does it say to do that in the transmitter tuning procedure in the 520 operator's manual?

The transmitter tuning procedure says to set the meter to ALC, Mode switch to TUNE, then key the transmitter using the SEND switch then adjust the DRIVE control for a peak meter indication. Next, switch the meter switch to IP, leave the Mode switch in TUNE then adjust the PLATE control for a "minimum" meter indication not a Peak meter indication.

As a recommendation you might consider reading the TS-520S operator's manual, page 20 paragraph 4.11 titled "TRANSMITTER TUNING".

Sorry, no, peaking the RF is where the problem is. Using the plate and load.. The meter was pegged. Neither the plate or the load would bring it down sufficiantly. I had to lower the RF voltage to bring it down to 2/3 scale. And thats not even peaked. Thats almost a dip...

I have been sitting in front of my TS-520S, with the manual open, and on my lap. Following the :

Mode: USB Meter : IP 60ma
Mode: Tune Meter : ALC Peak using Drive
Mode: Tune Meter: IP Dip Plate
Mode: CW Meter: RF Peak Using Plate / Load

Im sorry if I was confusing in my first post, Its in the "Mode: CW Meter: RF Peak Using Plate / Load " Stage that my meter is pegged. The first 3 stages are A-OKAY. Again, the meter is pegged, unless I turn down the RF Voltage, at that point my AT-180, on FWD Power, is only showing ~50w peak. Where as 3 days ago, It was showing 100-120w.

Has something finaly gave out? Do I have to start digging around or bad caps, or tubes?

thanks again, and Sorry for the confusion.

Are you tuning into a (real) dummy load?
When your meter is reading full scale in the "RF" mode, switch to Ip and what does it read?
You have verified that your tubes are working (60mA resting current), and you reached resonance (Ip dipped).
The "CARR" control is what you are calling "RF Voltage"? A little confusing to me.
Why are you using the AT-180, instead of a using a better power meter?

John,

Did you read page 13 where the RF VOLT CONTROL is discussed (#1 shown in FIGURE 6)? Notice the discussion on page 6 says to adjust the RF VOLT pot for a

"2/3" scale reading during CW transmission"

The RF VOLT pot that controls the REL PWR meter switch display, is located on the left side, rear pot, see figure 6 on page 13. There is a panel with 2 snaps that is removed to adjust the RF VOLT pot. Besides the RF VOLT pot there is the VOX GAIN, ANTI VOX,

There is no meter scale for the REL PWR meter display. You simply key the transmitter in CW mode at full output power into a 50 ohm dummy load then adjust the RF VOLT pot so the meter "pointer" is pointing about 2/3 of the meter pointer travel. A good reference is the meter pointer is pointing to the large tick mark between the top scale 200 and 300 indicators.

A) Yes, I am tuning into a TRUE 100w Dummy load
B) I will check the IP after I do a tune up this evening and reply back with the reading
C) When I start the tune up, in USB Mode, and Meter switch on IP, I am getting a rock solid 60ma
D) There is an RF Volt adjustment on the side panel, Under the cover, my CARR is set at half way, so in the 12 O'Clock Pos.
E) My other Power Meter is an MFJ Meter, SOOO not a better meter, I am in the process of looking for an AT-200 to mate with my TS-520s station, but have not ben able to find one yet. And as far as everything I have read, and compared, the AT-180, and the AT-200 are the same unit in a differnt series matching case. Also... Im not made of money, and here in Canada we are very limited in our access to equipment, especialy in my QTH... I live on an Island. We have to ship everything in. :)

Tonight, I will attempt to record my procedure, and post it on YouTube for any suggestions. I am folloing the book, to a "T". but Im sure there is a lot ot learn. This is a learning process... I can certainly atess to that!

John,
You can easily check your driver(12BY7A)tube and your finals:
During your tune up...can you get full meter swing with the meter selector switch in ALC (and the rig keyed) with the "CAR" control and with some room to spare, especially on 10 meters? If not, the driver tube is getting soft..and will soon need replacement.
When dipping the plate..is the plate dip quick and sharp? If the dip is shallow and broad...the finals are going.
With rig tuned for max RF output, meter in Ip, key rig, does the reading stay steady? If it falls off...failing finals.
There maybe other problems within your rig..but start with the above. I am guessing that this rig is new to you. Check also the HV(high voltage). You can use the front panel meter set to HV and flip the send switch. Your "resting" HV should be approx 850+ volts, with the rig tuned for max RF output..the voltage will sag a bit but should usually go no lower than about 750 volts. IF you get only 1/2 of any of the above voltage readings...STOP! You have more that likely lost 1 of the HV capacitors. Those are the tall round things on the top of the chassis in the middle...some are grey some are black. If you continue to operate with that problem...things will only get worse. As stated prior there may be other problems...but one thing at a time. Let us know what you find

John:

You may not be able to just simply set the RF sensitivity pot to 2/3 scale when loading to 100 watts into a 50 ohm dummy load and leave the pot at that setting and never have to touch it again.

When loading into your antenna(s) you may have to adjust it to keep the indication on scale so you can see the peak. It depends on the kind of antenna.

If loading into high resistance and/or reactive load you may have to readjust the RF sens pot to keep it on scale so you can see the peak. Also, the higher you load the output power level the higher the RF voltage will be presented to the RF detector divider resistors and the higher the meter will deflect.

If you have an external wattmeter why not just forget using the RF relative power position of the rig. Leave the meter on Ip and just load for maximum RF output on your external wattmeter without exceeding approx 200 ma Ip.

I have a paper on my website http://www.k9tw.com http://www.k9tw.com that explains why I recommend new folks use an external wattmeter to load their hybrids. Makes the process so much easier and very evident if you have a problem. If you unscrew the coax off back of your rig you can use the RF relative power position to make you think you are loading your radio. Not recommending you try it, but the condition can present itself if you ever have an open or very high resistance anywhere in your antenna system.

Terry K9TW

John,
an addendum: using the front panel meter...check the VOLTAGE and the CURRENT and apply the formula: P(power)= I(current) X E(voltage)
  this will give you approx power INPUT..then divide by 60(percent efficiency of the final amp---on a good day- usually lower)) to get approx power out

Joe,

When in ALC I can get a FULL Swing of the meter with absolutly NO problem at all. And when Im dipping the plate, its a smooth sharp dip, and sometimes difficult to get it to the lowest due to the sharpness of the dip. It starts off slow, but the closer and closer I get to the dip, the faster the rate of fall and rise. to a point that its very sharp drop. But its not always a very deep dip, sometimes it is, but when I move to an other band the dip will be shallower or deeper. I have not monitored the HV side yet. But I for sure will tonight. I do all of my tuning into my dummy load, once done, I tune my antenna using the AT-180. Im using a G5RV at this point, and Im lucky my HOA is letting me do that.

The rig is new to me, Im more of a modern rig kinda guy, with the exception of my Heathkit collection. but I rarely use them on any kind of regular basis. Thank you for your insight.

I think you all will make this easy to solve, and even easier to make me look the fool! lol

I spend about 3 hours last night going thru this rig, a lot of testing as per your previous suggestions, as well as via the service manual. What I found was that :

A) There is very little ref. to how to set or even adjust the CAR, other then to tweak it along to give a gain adjustment.
B) The Bias control also affects RF output, along with the RF Volt control
C) Chances are the first few days I was using the rig, it was competing with oxidation, and other issues.

I had taken the driver tube out (what a hassel) the chimney was a real pain to get off, as it had corrosion on the inside beween the "Keeper" and the chimney its self. I cleaned the socket, and the tube pins with some deoxit on a q-tip and tooth pick. This may be brightened everything up.

I was able to adjust the RF Volt, and Bias controls in harmony with the CAR control to get the tune up to spec out properly. And in the end, my watt meter was indicating 110w at 2/3 RF Scale reading. So I think that this was a successful night... Now to get the bulbs replaced so I can see the meter and dials when Im a hermit in my radio room.

Today I finished recapping my TS-830. Replaced all elkos with new 105deg. types and checked connection and possible shorts with continuity checker. Replaced the stressed parts in the PA. Used paper stickers on each and every molex connector with connector number on them to prevent putting them in the wrong socket. Cleaned and inspected each PCB for visible cold solder joints (didn't find any...). Removed the band switch wafers, cleaned them with an ultrasonic cleaner, measured contact resistance and put them back. Didn't touch any slugs.

Perhaps it was foolish to hope to do major surgery, reassemble everything and expect the rig to work.... unfortunately the RX is as good as deaf (didn't check the TX, first things first...)

This is working:

- (small) success: no blown fuse when switching the rig on.
- meter light comes on, counter shows plausible frequency corresponding to band switch and VCO turn. Checked "fix" switch (is off).
- low, mumbling sound is heard in the headset (no speaker, top is off). No typical band hiss, only low audio frequencies, but no hum. No marker beep. No reaction to band switching.

Intended procedure:

- check all connectors and plugs visually (again...)
- check major supply voltages for RX (don't care at this point if HV is correct...)
- inject test signal into audio amp and go backwards until it is gone (I have a old school signal injector 1000Hz with harmonics up to several MHz...)

Any more ideas and suggestions?

Martin DB2MJ

John,

The bias adjustment is an adjustment of it's own. You do not adjust it along with other pots to achieve a variable RF power output at the antenna connector. The bias adjustment is discussed and shown in the operator's manual, page 20, paragraph 4.11 titled "TRANSMITTER TUNING". This adjustment should be the first adjustment you perform before attempting to transmit on the air. Once you set the bias pot as outlined on page 20 paragraph 4.11 in the operator's manual you do not touch the bias pot again unless you perform work on the final amplifier or change final tubes then simply check the 60ma idling current and adjust the bias pot only to bring the idling current back to 60ma.

The RF VOLT control/pot has nothing to do with the actual level of power output you see on your watt meter. The RF VOLT pot simply controls the RF level displayed on the meter with the meter switch set to RF. Again the RF VOLT pot has no control over the level of RF output you see on your watt meter.

The CAR control varies a DC voltage applied to the Balance Modulator (BM). As the CAR control is rotated CW or CCW, the DC voltage increases or decreases, producing an increase or decrease in the CAR UNIT RF signal that appears at the output of the BM. The CAR control is used in TUNE and CW mode ONLY. The CAR control is disabled in USB and LSB modes.

I recommend you spend some time studying the "Circuit Description" section in the operator and/or service manuals so you get a better understanding of what's taking place in the transceiver.

In the 40 years I used my TS520, I rarely used the RF position of the metering. I went by the plate current (Ip) mostly and only used the ALC metering initially to set the driver tuning after changing bands.This plate current tuning habit came from using all tube transmitters with PI network output, for almost 20 years before I ever had a hybrid rig. If I had an SWR meter connected I almost always noted the peak of output power corresponded with dip of plate current and with the loading set for the rated final tube plate current !! My radio is Ham Radio...CW is Real Radio

Why do you think Kenwood spent the money for the RF relative power position?

You were loading Class C transmitters before your KW and they are very different beast. Your KW is a Class AB1 linear amplifier. It is a grid driven tetrode and plate current in a tetrode is not a good indicator of resonance. KW acknowledges that in the loading instructions for the TS830 when they tell you in a Note at the end of the loading instructions to "simply adjust both the Plate and Load controls for maximum output as described in both the tune-up procedure and summary Table 4-1".

Where in the your KW owners operating manual does it tell you to Dip and Load?

So you also modulated with no regard for ALC indication. Kind of selfish and sad. Also very poor thing to teach new people.

Trying to tell when Class AB1 is fully loaded by looking at Plate current dip is not the optimum way to load. The dip will be very shallow and not easily discernable. The output power peak on an external wattmeter or the RF voltage peak on the built in RF detector on the other hand is very obvious and well defined.

I strongly recommend that all new owners literally follow the Loading and the Operating instructions in the manual and your Finals will last a long time and you wont be subjecting your fellow hams to adjacent frequency splatter.

Can you load a KW hybrid with the old Dip and Load method? Sure you can. Is it the method that KW engineers describe in the manual? Of course not.

I suppose you think that peaking the ALC is same as setting 3 to 4ma of grid current that you did for 40 years on your Class C transmitters? Not remotely close. You are tuning input and output LC networks for maximum RF voltage swing at the control grids of the Finals. No grid current in a Class AB-1 final. Actually about 40ua of grid current which causes ALC amp transistor to buck the ALC bus voltage and drive the bus down causing the meter to read up scale so it provides an easy way to know when you have maximum RF drive voltage at the finals (Mixer and Driver Tank circuits tuned to resonance).

Not sure why I waste the energy. Old habits like myths and lore die very hard.

Thank you Mike,

I have been reading the manual, and service manual. I have been following procedures as outlined by these manuals. Im not really sorry if Im going about things hap hazzardly, Im going about them as the booklets outline, in the order that the problems have popped up. One thing at a time, No rushing, and I dont want to fry any components as I go along either.

I understand the relationship between the adjustments, and their use. The block diagram has been of great help. I am new to these hybrids, and it is very much a learning experiance. Like it has been said, I wish to follow the direction of the book. Im a Soldier, that IS THE only way things can be done, in my eyes.

I am glad that with the adjustments that I have made, that I have been able to :

A) Keep 60ma
B) Get a good dip on the IP
C) Keep ~100w output
D) Maintaining an HV of 850+v

All as per specs in the book, and on all the bands I have tuned up on... into a dummy load of course. And I know that a REAL antenna will present new problems or variations. I will be ready for this when the time comes to start moving around and TX on the bands.

I am new to this, In fact this radio is a number of years older then I am....

Thank you again everyone,

John Brent

You're correct in that there isn't a plug like what is needed on the 520/820. In its place is a switch on the external VFO socket. I believe its S21 on the schematic (I don't have a schematic in front of me so the number may be off a bit). There's also one on the transverter socket as well.

Evening Charlie,

I do have enclosed a picture of what type I need

Hope you can receive the picture.

Otherwise or if not received it,give my your personal E-mail,I will sent it to that address also …

Like you prefer..

Regards Jean ON4AEF.

Hi Jean

Not sure if this is the same as the 510. Mine says PS-511S, is brushed silver with a grid of holes covering most of the front. This is a ps/speaker enclosure set up.

Charlie

On Wednesday, April 22, 2015 10:28 AM, "'Behiels jean-Pierre' <mailto:on4aef@...> on4aef@telenet.be [TS-520_820_530_830]" < <mailto:TS-520_820_530_830@yahoogroups.com> TS-520_820_530_830@yahoogroups.com> wrote:

Hi Charlie

I could not directly follow hi ….

Does the TS511 is the same supply as the TS510 transceiver supply called the PS515 ?

I presume,you mean the TS511 supply is the same supply as the originally of the TS515.

But I really need the originally one from the Kenwood TS510 transceiver…

Inside they are quit identical but outside the boxes are different …

I look forward.

Regards Jean ON4AEF.

The PS-511 and the PS-510 are NOT the same in cabinet appearance, Jean
is correct. You can see the difference by searching for "PS-510" images
in google.com.
Here's a good view of one:

One of the first things you do when repairing a faulty circuit is "check supply voltages". I adjusted the 9V and 3.6V voltages to about +/- 10mV tolerance. The next thing was checking every board using this 9V. All had the correct voltages.

There is a -6V rail running through the unit. I checked it first at the counter unit (ok) and then the IF board. BINGO! No -6V at the IF board. I routed a short wire from the counter unit to IF board and the RX came alive... much better! The marker is clearly heard (a little off, about 1.2 kHz low) and only S7, but at least a sound...

So, off to a better future... I'll keep you informed.

Hi folks

TS-830S:

1. Mode to CW-W, Vox gain to ON, key down and nothing happend.

2. Mode to CW-W, Vox OFF, SEND switch to send, Key down -> Power OUT but no sidetone

So I think I have the "No sidetone when keying CW, VOX doesn't work on CW" Issue!!!

I've changed the Q1 on the AF Unit but it's the same situation.

Any ideas / suggestions??

Hi Martin,

Congrats. Have a look at the -6V rail input from the molex connector, most prob what has happened is possible cracked track with removal of board when replacing caps, but if not then fairly easy to fine where -6v is missing. You never mentioned if you replaced the HV caps or relay. I do this on all radios that hit my bench, as matter of prevention instead of repair. Whilst you have lower level of calibration marker, this may or may not have changed since replacing all caps. You should undertake full alginment once you have the radio working.

I had a similar problem with a 530s, -6v was missing, this was due to gorrilla heavy hands cracking -6v line on counter unit in 4 places, when cutting the warc band blue wire.

Take a look at Conn 2 on Audio board. Gently wiggle or remove and re-plug. Also, clean and exercise VR-1 sidetone level adjust trimmer pot.

Can also measure Key, STB, and STE. Approximate dc voltages are:

STB = 113.7 Rx and 115.2 Tx (basically same voltage in Rx and Tx)
STE = no voltage. Resistance to chassis ground in CW should be "0". Can temporarily ground STE if indication that you have bad mode switch contacts.
KEY = -67 Rx and -.3 Tx

On rare occasions D1 can be bad and if so wont complete the RC phase shift network feedback path to base of Q1 and no oscillation.

Rule out dirty pot, bad connections and/or missing voltages before pulling AF board and start replacing components.

Lastly, if you have an O-scope can look at TP-1 and should see approx 3.5 vac P-P 740hz sine wave side tone signal in CW mode with rig keyed by code key in the jack.

Hello and thanks Terry

It seems that the TS-830S has 2 problems:

No sidetone No CW-VOX and therefore no carrier
SSB Vox working perfect! I have only a CW carrier when I push manually the SEND switch an key the "CW-key".

Where to measure Key, STB and STE??? And NO I do not have an O-cope!

Hi Dave,

I did a full recap (all >100 elkos), including the HV caps. The -6V line runs from the counter board to a wire wrap post behind the front plate (near the AF board) and one of the wires soldered there was broken. Braided wire is prone to break when soldered in, that's why everyone is crimping these connections today. I found the loose end and the rest is history :-)

The first owner of the rig used it mainly for AMTOR and replaced the standard antenna relay with a heavy duty vacuum relais and the smaller omron relais with reed relais on a small custom board. I don't think I'll ever need worrying about relais contacts...

51939. Low Output On Portion of 3.5 Mhz Band TS-520S

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-04-24 20:23:14 UTC
From: ne5dx@...
Topic: 51939 Message: 51939

Hopefully, someone may have have a bit of insight into this problem. This TS-520s has a fresh set of NOS Sylvania tubes, neutralized, all coil packs aligned, idle current set with excellent receive. Using a Bird dummy load and Bird watt meter then a good resonant antenna, I tuned-up on all bands at the top and bottom of our operating ranges to 200ma of plate current to get a comparison. Output on 160m - 15m (minus 80m) was 100+ watts consistently. 10m is at 85 watts across the board and has good ALC action.

Now 80 looks like this:

4.00mhz 100 watts at 200ma.
3.90mhz 90 watts at 200ma.
3.75mhz 35 watts at 200ma.
3.50mhz 25 watts at 200ma.

Above 200ma there is a bit higher output certainly, but obviously there's a problem so I didn't keep it at 200ma for long at those lower freqs. I tested the rig with an old set of tubes (pulls) before the new set was installed and coil packs aligned. It behaved exactly the same way on 80m.

I'm pretty certain the rig had been left in transmit mode with the heaters off for an extended length of time, possibly days. The tubes were totally dorked as well as the cathode resistors. Other than that, I can find no cooked caps or obvious damage, no signs of arcing or cold solder joints and the band switch looks very good. It simply looks like a TS-520s that had been in storage for 25 years: Very very clean.

The person I got it from said it was on 20m where it pretty well stayed since removed from storage, so, I assume he really doesn't know if 80m ever worked correctly! I don't think he owned a watt meter and probably tuned by the seat-of-his pants anyway.

Thanks in advance for any help..

de Don, NE5DX....EM10ME

Where does the S meter peak on 80 meters with the Marker signal with the Drive Control at 1200? It should peak close to 3.750. If it does not leave the Drive control at 1200 and swing the VFO up in frequency and see if S meter is peaking around 4 mhz.

If it is peaking at high end of band then do this:

Set the VFO to 3.750 and perform the Coil Pack adjustment for just that band. This is an easy first step to see if someone peaked it higher in frequency. Follow the directions in the Maintenance Section 6 of your Operating Manual.

After you do the Ant and Mixer coils using the Marker signal in Rx mode then turn off SG switch and turn on the Heaters and peak the 3.5 Drive coil. You do that in CW mode with Car Pot advanced for ALC indication and Drive control at 1200 and peak the coil for max ALC indication.

Then load the rig at 3.750 and see if you now have 100 watts out at approx 200ma.

If no improvement may have a fixed padder cap problem.

Topic: 51943 Message: 51943

The reason I am posting this is because I have received numerous off List emails about my response to JD about using Dip and Load method and not using the RF Relative Power meter position to load a KW hybrid. About 70% support me and the others bring to my attention that other KW techs have loading procedures on their websites that use the Dip and Load method including Ken K4EAA who is the most respected and quoted of all the Techs.

First of all Ken and I are friends. There are things that he and I just have to agree to disagree on. Things like cathode resistor "fuses", using the Plate Load control to reduce rf output power, and Dip and Load. It is OK to have professional differences of opinion and I dont think we are that far apart on this one if you read his procedure closely. Secondly, I understand that it makes it hard for new and old alike to decide whose counsel to follow. That is a challenge for all of us when we Google on any topic whether its ham radios or medical advice.

All I can tell you is that I stand by my advice that everyone should literally follow the Loading steps in the Operating Instruction manual for your particular model Hybrid. You will find that everyone of the procedures after making that initial plate current dip will direct you to use the RF Relative Power meter position and to alternately adjust the Plate and Load controls for maximum meter deflection.

The TS830 procedure is a bit convoluted as they have you go back and forth from Ip to RF meter positions to ensure not exceeding 265ma. Not a bad idea when done loading for maximum RF Relative Power meter indication to check Ip to ensure not exceeding maximum plate current. Really if key down time is properly limited there is no real concern if you are at 200ma or 225ma. If you are going to run SSB or CW modes (the design modes) then the duty cycle is so low you will never see that level of plate current ever again while speaking into the mic or sending code. Un-processed audio is around 15 to 20% duty cycle and CW at 13 to 15 WPM is around 40% duty cycle. I think we have probably put way too much emphasis on not exceeding 200ma or 225ma when loading when the emphasis should be on no long off resonance key down times with long being defined as greater than around 10 seconds or so. Long key down times are just as hard if not harder on the Driver tube that is running flat out in Class A. Long off resonance key down times, loss of operating bias, and running high duty cycle modes without reducing plate current are sure ways to produce measurable reduction in tube life. Oh boy likely another can of worms!

If you want to see the RF Relative Power meter indication loading process demonstrated the best video that comes closest to the correct method is Alan Wolke W2AEW TS-830 You Tube video #153.

I will not respond to this topic on the forum any more. What I will ask in return is that you put on your thinking and questioning attitude cap and read a few of the operating manuals for SSB transmitters and transceivers of the period that ran a pair of final tubes biased for Class AB-1 linear operation. You may find some that employ the dip and load method, but I submit they will be in the minority.

Try the Heathkit Marauder, the Yaesu FT-101ZD, and the Drake TR-4 for starters. There are others. All three of these radios have an RF Relative Power meter position and all three have loading instructions that direct the owner/operator to load for maximum RF meter indication and not dip and load. Ask yourself why this would be. Is it just coincidence that design engineers from different companies be like minded when it comes to instrumentation required for proper loading of a SSB Class AB-1 linear amplifier?

Here is an excerpt from the Heathkit Marauder manual on the "how and why" to load.

FINAL AMPLIFIER PLATE TUNING ... All tuning of the Final amplifier is performed in the Relative Power position of the panel meter. Due to the low amount of grid drive used in linear operation, the final circuit cannot be tuned properly by a dip in the plate current. Resonance is indicated by maximum power output. The Plate position of the meter is used for adjusting plate current when operating AM and to give the operator an indication of the amount of final current being drawn at the completion of tune up, which will be 200ma to 250ma. The Loading control, as well as the Final Amplifier Tuning control, is adjusted for maximum power output as indicated in the Relative Power meter position.

I will let you read the Yaesu and Drake manuals loading instructions for yourselves.

In addition to watching W2AEW video you can go to my website and read why I recommend taking it one step further and putting some real numbers to the RF Relative Power loading method by adding an inline wattmeter.

Thanks to those who wrote in support and I am OK with those who disagree or question why I would challenge Ken or other Techs who have Dip and Load procedures on their websites. If you read Kens procedure closely you will see he really has a "hybrid" approach as he does finish his dip and load procedure by using the RF relative power meter position for what he calls "fine tuning".

Again sorry for beating this horse to death. If you are a Dip and Load person have a ball. If newly licensed and/or new KW hybrid owner follow the loading instructions in your manual. With a little practice you will be able to load very rapidly and be able to tweak the loading on the fly as you QSY around the band. Also, in SSB mode do pay attention to the black printed ALC range and adjust the mic gain to keep the ALC indication within that range on voice peaks. It is true that it is hard to over drive the TS820 and TS830 as they employ RF negative feedback, but staying within the ALC range is good operating practice to ensure you are not splattering on adjacent QSOs on the band.

Topic: 51939 Message: 51944

So you are telling me that at 3.750 mhz you can peak the Drive control close to 1200 for a full scale deflection on the ALC meter position with the CAR Level Pot no more advanced than 1200? By full scale I mean peg the meter and not far right hand end of the black printed ALC scale.

If so that means that you have approx 45 rms rf volts of drive at the control grids of your finals and low RF output power is not due to having low RF drive.

This means problem would appear to be in the PA cage.

It would appear that your Plate block and RF bypass capacitors are ok based on the output power you are seeing on the other bands. RF plate choke would seem to be good as well. There are no series resonant holes in a good RF plate choke at 3.750 mhz. I assume it shows no signs of overheating.

Only other component that comes to mind is the fixed padder caps that are switched in parallel with the Tank capacitor and the Load capacitor, but usually when they are bad the Plate and Load air variable capacitors dont point to normal positions for a given band. Does the Plate capacitor point to usual position for 3.750 or is this radio new to you and no point of reference as to what is normal? I believe that you said 160 loads normally so that kind of rules out the padders because 160 uses the 80 meter padders in combo with additional ones.

Also, I have seen a few Plate loading caps where the lock nut on outboard end has backed off and allows the plates to move axially and short out at some point in the rotation. Usually can see the white paint has cracked or flaked off. Grasp the shaft and move it axially and watch the plates and make sure no motion.

Ideally would be best if you could get on the control grids of the 6146 finals with a RF probe (3 diode) and see what the RF drive is doing. If it is staying from 40 to 45 volts then you know it isnt a drive problem.

Terry K9TW

Don

One other thing. Would be rare but take a look at your 470 uhy L7 safety choke at output of the Pi network. See if it looks discolored. Might try lifting one end of it and try loading at 3.750 mhz to see if improvement.

If not be sure to reland it. Important to have it in circuit as it provided dc return so the Tank capacitor doesnt charge up to anode supply and arc over and it also will blow the fuse if the plate block cap is leaky or shorted so no high DC voltage at the SO-239.

Terry K9TW

51946. Re: Low Output On Portion of 3.5 Mhz Band TS-520S

From: ne5dx@...
Topic: 51939 Message: 51946

Yup, drive at 12:00 (which is peaked) and CAR at 12:00 and I have full meter deflection of ALC.

I noticed that at 4.000mhz when I dip the plate, the dip is pronounced with a good increase in power. Pretty well normal, in other words. At 3.900 I can still get a decent dip, but not as pronounced and power is reduced. At 3.750 there is little dip, just current draw with low output. Below 3.750 there's almost no dip.

After your comment regarding the parallel caps, I double-checked my comment regarding 160m and see that at 2.000mhz it indeed seems pretty well normal, but at 1.800 it does produce full power although the plate tune is broad and no sharp dip. I did a quick tune-up before for my benchmark, saw full power at a reasonable current level and didn't go slow and easy to really see the process. I now recognize a difference. Also, at 2.000mhz, the pointer on the plate control "points"pretty close to 1.8 on the silk-screened scale on the front panel. At 1.800mhz the plate variable is much closer to full mesh, not near half-mesh as for 2.000. That seems odd since I'm using a good dummy load.

I will admit with all the hybrids I've owned, I've never used one on 160m, so I don't have a good feel for that band plus this is a "new to me" transceiver which had dorked tubes when I got it. I have no past experience with it.

So, could those parallel caps switched in for 160/80m could be part of the picture after all??

Terry,

Terrific post! Since our past discussions I strictly follow the "max output" prodedures for the KW and Yaesu hybrids, right by the book. This makes a lot of sense to me. I also follow Mike's advice to always tune the hybrids into a dummy load before going to the antenna as well (I watch the output power meter). Interestingly, tuning in this can result in power out exceeding 100W on the meter. I can get 120W indicated on the low bands on the FT-901DM (150 indicated watts on 160!?), which can be a little scary but the plate/cathode current reading (depending on whether a KW/Yaesu, respectively) is within parameters. I don't put an incredible amount of stock in this, as my MFJ-949E power meter is not a precision instrument, but tuning by the book nearly always results in exactly 100W out and the correct plate/cathode current.

Thanks for your ongoing support of the KW Hybrid group and all of us dabblers!

Dave

Terry...

I'll check L7, although physically it looks like it was manufactured yesterday...

I just had an "ah haaa!" moment!! I've been looking past this until now, when I realized it "just don't look right" so I pulled a couple more 520s off the shelf to compare...

The plate choke on the other rigs have 5 distinct pi sections all spaced out and squared up. The choke in this rig looks as if the bottom section is where it should be but the other 4 sections slid down and are crammed together.

I had mentioned in my first posting that I'm pretty sure this rig was left in transmit mode with the heaters off for days and the tubes were totally toast. Could there have been tremendous heat generated by these tubes and softened the binding agent used in the coil which let the top four sections slide down on the ceramic form??? Sounds "far fetched" but it's the only thing I've found not kosher so far.....

Thanks again...de NE5DX

New owner of a TS-820S, picked it up this past weekend at a get together. He thought there was more of it wrong than originally thought.
When I got it the LED display wouldn't light up. It took a few hours but I learned that the EXT VFO port needs the pin 8-9 jumpered so I made one and it lit up fine. Receives on all bands, although for some reason the 160m band refuses to receive, no LCD display, no receive. Sometimes it works, sometimes it doesn't (more often than not the last few days it hasn't worked). The rest, 80-10m all receive fine.
Still need a mic so I haven't been able to test any transmitting,although with a Tech license, I would still be limited for the time being (studying for my General now).

Yes this could be your problem.

I have never seen this happen on a TS520 or TS820 choke. With the sections slipped out of place it can alter the parallel and series resonance points as the "distributed capacitance" and "proximity effect" of the turns have now been altered. I would think in order to slip down some of the winding as also come unwound at least on the top segment?

Not sure if you can try to slip them back in to correct spacing or not? Apparently the lead wires between each segment are still intact. Since you have other chokes to compare to I would try to reconfigure and see if that fixes the problem. Check with Bob Mansker KE5FTF@mail.com to see if he has a good used pull.

You can make some home made Q dope by melting white styrofoam peanuts in Toluene solvent. Clifton Labs has procedure on his website. Becareful as solvent is flammable.

Sure sounds like unable to adjust the Tank circuit to resonance at the low end of 80. Not likely that the tap on the inductor is bad as you can resonate tank higher in frequency.

160 normally is a little different and many of us dont have much experience with it. It does tune a bit different.

Might do a visual on the padders. Sometimes they will be darkened and even split or cracked.

If you have a 100pf 1kv disc ceramic cap could temporarily tack it from tank cap to chassis ground and see if it makes any difference. C5 is the cap in question. I would think if bad would affect all of 80 meters unless it has just changed value? It is hard to get Type 1 caps for this application so they just use a Type 2 and increase the dc voltage rating to 3kv. For quick test could probably get by with a 1kv.

Mike….

I would apply a drop or two (No more---don’t use the spray, too messy!) of DeoxIT to all the wafer contacts in the band switch. Then work the band switch through its arc a few times. (With the radio ***OFF***)

(Much success in getting your General!)

Joe – W7RKN

Subject: [TS-520_820_530_830] New owner of TS-820S

New owner of a TS-820S, picked it up this past weekend at a get together. He thought there was more of it wrong than originally thought.

When I got it the LED display wouldn't light up. It took a few hours but I learned that the EXT VFO port needs the pin 8-9 jumpered so I made one and it lit up fine. Receives on all bands, although for some reason the 160m band refuses to receive, no LCD display, no receive. Sometimes it works, sometimes it doesn't (more often than not the last few days it hasn't worked). The rest, 80-10m all receive fine.

Still need a mic so I haven't been able to test any transmitting,although with a Tech license, I would still be limited for the time being (studying for my General now).

For some time I had problems with my TS520 (no S) not able to tune up on the low end of 80M, finally found a burned capacitor,(the one that is switched in parallel with the loading variable on 80M by the band switch). Replacing that cured the 80M problem. My radio is Ham Radio...CW is Real Radio

Terry...

I would have bet money the plate choke would have been part of this problem, but sadly no. I removed it, heated it with a heat gun and moved the sections back into place. I tested first and will dope later. But virtually no change...

BUT, I tacked a 100pf cap from the tank coil to ground as you suggested and BIngo! It tunes correctly.

So, I located C5 beneath the chassis and what did I find? I found the stationary contact on the band switch was rotated 90 degrees, obviously the movable contact couldn't mesh with it, so, no C5 in the circuit at all. It appears to have been like this from possibly, day one. There's no sign of tampering in that area, I can only assume it's been like this all along and never worked correctly..

Anyway, it's completely normal now and tunes perfectly. I appreciate your input, it took some head-scratching but you nailed it!! Next step is to dope the coil, install the covers removed and wrap-up the project.

About 90% of my enjoyment from Ham Radio is repair and restoration, My next project is probably a lost cause, but I want to try anyway. A TS-820 that was tossed in a swimming pool. Uhhhh, funny things can happen under stress! I guess Ham Radio wasn't very popular with the ex-Mrs of the original owner of the rig. Oh well, it was a freebie so if I can't resurrect it, there are some good parts!!!

Thanks for your patience Terry, this is probably a "one of a kind" TS-520 problem (along with the plate coil), but I certainly won't forget it for some time.

Thanks for sharing what you found. Yes it sounds like must have been that way from day one. In my experience the TS520s build quality is pretty good.

I would think should see 160 dip location a little different now as well.

Yes like you I pretty much never forget these unique problems.

Have fun bringing the 820 back.

I am aware of the allocations but I do not know CW, nor do I care to learn it or use it. Just one of those methods that I have no interest in, just my preference. So yes voice or data we are limited to 10m with a tech license. I have been playing with PSK, JT65 and SSTV since I can do those contacts while I work (from home as a server admin). Currently have it setup with a homemade circuit board for audio and PTT using the RTS on COM port, going to my Realistic HTX100, mostly used it for PSK so far, but I made my first JT65 contact earlier today.

Depending on a few factors (obviously, it's best to have no live voltage when dousing ist), how long it stayed wet and if the water in the pool was saltwater or not it is very possible that the rig will work again.

Here is an article from the Tectronix publication for employees about the washing station for scopes coming in for repair... they bathed even tube scopes before servicing it. I did this to several old pieces of hifi equipment from the late 1970s with best results (remove top, put it in the shower, rinse it, spray a mild detergent on it to remove crud and dust, rinse it again. In winter, put it on a full running radiator for 1-2 days, in summer leave it to dry in the sun for a few days).

Very interesting Martin. I've bookmarked this info for future use. Fortunately the TS-820 wasn't submerged long (as I understand it), but it happened many years ago and the transceiver has been parked on a shelf in my shack since I found it. I've pulled all the boards and will remove the front panel and vfo, trying to reduce it to a bare chassis as much as possible.

There is some rust on the chassis in spots, but I've restored vintage equipment in much worse shape. I haven't inspected the digital readout yet, since this area seems to be a weak spot at times, I am concerned about damage there. At least it will be a good time to re-solder any area needed attention. It should be an interesting project. Guess I've postponed it far too long....

Thanks again for the info and 73.

Hi Mike, First time I've seen this particular QRP circuit.
I'm not a tech so what is the advantage of using your QRP circuit over a simply 220k pot and a 9v battery?
I use the simple voltage divider circuit everyday with PSK on my 830S. Am I stressing the rig?
Many thanks for your advice and tutelage. Appreciate what you do.

Hi Tom,

I could be wrong but I don't think I replied to your questions.

My QRP circuit provides a bit more linearity when adjusting the pot. A 2N3904 or 2N2222A can be used.

I'm surprised you are using a QRP circuit for PSK. You don't need the QRP circuit when operating PSK or other sound card modes. All you need to do is tune the TS-830 for maximum power output as you normally do. You adjust the MIC gain for normal sideband voice transmissions, ensuring the ALC doesn't exceed the top of the ALC scale but mid ALC scale is good, then don't touch the MIC gain. Connect the sound card interface to the TS-830, place the software in transmit, and adjust the sound card interface transmit audio level for approximately 20 to 25 watts, that's all you need to do. You do not need the QRP circuit to operate low power PSK, simply adjust the sound card interface transmit audio level. If you are not using a sound card interface, simply adjust the computer's "volume" (headphone) level to achieve the same 20 to 25 watts output. Again, you don't need the QRP circuit.

Mike,
Wow! I didn't expect that answer!

Just getting back into the hobby after being dormant for nearly 30 years, so read H. Ward Silver's book, Ham Radio for Dummies to help me get back up to speed. In it, discovered PSK. Further reading on the subject indicated that PSK is a low power mode.

So, searching for the answer to get a good quality SSB low power signal out on PSK with a hybrid, I found articles on QRP in the TS-830 Survival Guide edited by Olaf Rettkowski, DL9AI.

Here's a quote from the Guide: "On SSB, turning down the mike gain is a very poor way to reduce output power because doing so defeats the transmitter's ALC system. Thus, when you turn down the mike gain, you cannot assure any particular peak output level, and you're also turning down only the voice modulation content of your signal; the original carrier suppression, unwanted sideband suppression, miscellaneous transmitted noise, spurious and so forth are not adjusted "down," at all, but remain as they were."

So I made the heroic assumption that in order run PSK and produce a high quality signal, I needed to make the QRP circuit that plugs into the ALC pin of the Remote Socket on the 830S and preserve the excellent native modulation, suppression, etc., in the 830S.

I run a SignaLink USB hooked to a Win7 PC. So, I have a lot of control of transmit audio. I get really good signal reports with the QRP circuit, even had a guy in PA send me a pic of it on the waterfall. I've been told I'm the strongest signal on the waterfall and I typically run 10-15 watts. This I attributed to the 830S outstanding SSB performance and the QRP circuit.

I realize that we are talking, I think, about two different controls here: using mic gain to reduce power vs. using sound card audio to reduce power.

So, Mike, please verity, are my assumptions wrong? If so, I sure made it harder than needed to get on the air with PSK!!

Remember, I'm not a tech, just looking at a schematic or block diagram can give me a headache.

Again, many thanks for what you and the other super smart guys do for the rest of us mortals that have to learn things the hard way. And I must admit that the block diagrams and the schematics are actually starting to make sense because of you guys in this group.

Tom,

I never said you should turn the "/*MIC gain down*/". I said you tune the TS-830S up for normal full output then set the MIC gain in sideband, USB or LSB, for normal sideband /*"Voice"*/ ALC indications. This is accomplished by speaking into the microphone at a normal voice level and adjusting the MIC gain for normal ALC indications. I then said once that is achieved you leave the MIC gain alone.

The TS-830S ALC meter, during PSK transmissions, should rest at zero. The PSK transmit tone level to the TS-830S is adjusted at the sound card interface or the computer's sound card "volume control" for 20 to 25 watts. ARRL says 50 watts but I've had excellent results at no more than 30 watts indicated with zero ALC indication on the transmitter's ALC meter.

The following link contains information on operating PSK.

http://bpsk31.com/

A link to the ARRL PSK page:

http://www.arrl.org/news/10-tips-for-the-psk31-digital-mode

I never use a QRP circuit when operating PSK but if that's what you want to do then that's entirely up to you.

51969. Re: [TS-520_820_530_830] Reduced Power Tuneup

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-04-27 14:55:22 UTC
From: Craig Roberts
Topic: 51793 Message: 51969

I concur with Mike. To operate digital modes -- including PSK -- I simply leave my TS-830 (and TS-940SAT) in normal SSB mode, plug my SignaLink USB interface into the MIC jack and limit output power to 30 watts or so with the SignaLink's TX control.

I don't mean to sound redundant or engage in "me, too"ism, but simply wish to point out that Mike's not alone in his simple and fully workable operating procedure.

Have fun!!

51970. TS 820 Final Cage Components

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-04-27 14:39:23 UTC
From: rolf.vainio@...
Topic: 51970 Message: 51970

Hi,
Restoring a TS 820 S into working order I am using ready assembled kits to replace components to ensure that I get them right.
My Final Cage repair kit has two items out of a total of three for which the specs deviate from the circuit diagram of the TS820S. With my limited experience I dare not tell whether two of the components are safe to use or perhaps wrongly specified, so here my question:
- 0.001 microF door nob cap is OK, same value in diagram.
- .01 uF 2kV cap seems off as specs request 0.0047 uF .
-Same kind of deviation with 6.8 uH RF choke, my circuit diagram specifies 3 uH. My question, is it OK to use these two latter componets ? The cap and the choke would seem to fit the specs of the TS830 but are they not too much off specs to be used in the TS820 ?

51971. Dial Lamp replacement?

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-04-27 21:21:23 UTC
From: john.brent@...
Topic: 51971 Message: 51971

I have replaced the lamps in the meter, REAL easy, and LOOKS AWESOME!! 3.6v 20ma Ultra Bright White LED's and a 470ohm resistor.. BAM Sexy white meter.. now the dial looks yellow and gross.. not to mention one of its lamps is out anyways. What is the trick to these? Do I have to pull the VFO out? I DON'T wanna do that unless I have too.

51972. 2nd CW filter, TS-830s

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-04-27 21:44:38 UTC
From: zehrhj@...
Topic: 51972 Message: 51972

This afternoon I installed a second 500 Hz CW filter (YG-455C) in my TS-830s. Cascading two filters definitely narrows the skirts - almost too much for general use. So I repurposed the DH switch to switch the second CW filter in when I need it. Now I can use it as I did before, in W or N, but can also switch in the second filter when I need more control. I'm quite pleased so far.

In the process, I discovered broken connections to the IF board on one of the connectors. I'm glad I found and was able to repair that. It would have definitely given me grief in the future.

My friend gave me a digital clock he built from a kit and had failed a year later. I was tasked to see if it was repairable. Yes, I found a shorted filter cap in the 100 V power supply section and replaced it and a diode that looked stressed. When I tried to return it he had already gotten a new clock with a bigger display. He told me to keep it or trash it or strip parts off it.I made it a part of my hamshack and it has been steadily ticking off the hours, minutes and seconds of UT for for me for well over 45 years now ! My radio is Ham Radio...CW is Real Radio

Subject: [TS-520_820_530_830] Re: DG-5 Digital Display With Heathkit SB-xxx Gear?

  Thanks, Tim,

I really don't like the Heathkit SB-650 very much. It's big and clunky and uses Nixies. Yes, I know Nixies are all the rage these days with the young kids building digital clocks, etc, but I grew up with them in everything before 7-segment LEDs became popular. Can't say I was ever very fond of them. I have an SB-650, but I'd rather not use it.
Am I right?

Thanks!
Mike, WB0LDJ

51979. TS 520S no bias update

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-04-29 11:27:28 UTC
From: beeson.neil@...
Topic: 51979 Message: 51979

Just to let you all know the update on the 520S with no bias. I replaced the cathode and screen resistors and found 2 cracked solder joints on the 12by7a socket, replaced tx/rx relay and did heaps of testing. The one thing that suprised me, the antenna relay as soon as I replaced that she came back to life. So bias is now 60ma (and all other radios set to 60ma),HV is 850 and it tunes to 120w CW sweet as a nut.
So as I can tell the antenna relay wasn't resetting causing all the problems.

Thanks for all the advise given

My rig has a Kenwood M50 mike. I have a cosmetical problem with it: it's plain dirty. There are patches of unidentifyable materials partly blocking the grille and it just seems to call for a good cleaning.

Does anyone know how to disassemble it without damaging anything inside? I'd really like to put the whole thing (minus innards) into my ultrasonic cleaner...

Martin

51981. Re: [TS-520_820_530_830] Taking apart Kenwood M50

Yahoo group: TS-520_820_530_830 (2015 — 2016)

From: Ken Winterling
Topic: 51980 Message: 51981

Martin,

The mic head and the connector are both screwed then glued into the body. You need to soften the glue then unscrew the parts counter clockwise looking at the head or the connector depending on which end you are trying to remove. In order to separate the head and connector from the body for placement of the body in the cleaning unit you will need to unsolder the mic head and remove the switch. Make note of the wiring before unsoldering any wires.

To disassemble the MC-50 (or MC-60) mic wrap the microphone body in an old cotton shirt/cloth/towel to keep from burning your hands. Do not use any tools to grab the mic body or parts or you will damage them! Using a heat gun or hair dryer heat the joint between the head of the mic and the body or between connector and the body. Keep trying to unscrew the head or the connector (counter clockwise looking down on the mic head or connector). The mic head or connector will unscrew after sufficient heat is applied. Again, do not use any tools to hold the mic body!

I am doing a little house cleaning and want to sell my Kenwood TS-820s and accessories.

Before moving forward, I will not ship the radio nor will I break-up the pieces.

I am only looking to sell to someone within meeting distance of Howell, MI or I am willing to bring it down to Dayton and meet you there on Friday (Hopefully morning).

I have:

TS-820s radio (5.5 out of 10 radio - call sign in top of face)
(Display works and I read about 65 to 70 watt on most bands)
MC-50 mic (6 out of 10 - works, no issues, signs of wear)
VFO-820 with cable (6 out of 10 - works, no issues)
AT-200 tuner (6 out of 10 - works, no issues, call sign on top of cover)
SP-820 speaker (3 out of 10 - cleaned up, sanded and painted, works, melted plastic front cover)
SP-230 speaker (7 out of 10) - works, no issues)

I have $900 into the above equipment. Please e-mail me direct at gigahacker@gmail.com with any offers or questions. I can provide pictures of any equipment. You can see the setup at http://www.qrz.com http://www.qrz.com @ N8NQN

51988. Hybrid Net Update (May 3, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-05-03 19:37:30 UTC
From: Mark Gilger
Topic: 51988 Message: 51988

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by me, WB0IQK. There
were 18 stations checking in under good band conditions.

We had the following number of radios checking in.

2 running TS-520(x)
2 running TS-530(x)
3 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-830S + Drake L-4B amplifier.

The Sunday net was run by me, WB0IQK. There were
12 stations checking in under good band
conditions. We had the following number of radios checking in.

5 running TS-520(x)
1 running TS-530(x)
2 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-940S + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome

as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total = 142, Sunday☐s total = 88
December 2014, Saturday☐s net total = 92, Sunday☐s total = 86
January 2015, Saturday☐s net total = 110, Sunday☐s total = 84
February 2015, Saturday☐s net total = 103, Sunday☐s total = 98
March 2015, Saturday☐s net total =80, Sunday☐s total = 51
April 2015, Saturday☐s net total = 59, Sunday☐s total = 29
May 2015, Saturday☐s net total = 18, Sunday☐s total = 12 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Hello, Dear group, I would really like to know of a good repair tech that would do a honest job. I have blown up my rig today, it has never been "on the air" as far as I know. I was cleaning all of the switches and pots with some Detoxit today so I thought that I would check the power supply. The covers were off and the speaker wire was in contact with the power switch lead, and you guessed it! Magic smoke from underneath and a couple of pops from other places. Mark one up for being stupid. So I need a good repair man. Thansk, Greg KM4HOY

Greg:

I don't know of a specific technician to recommend- although there are probably several who are members of this user's group- but might I suggest- "you", personally? There's nothing wrong with taking your rig to a "professional" to get it serviced, but this sounds like something that you might actually be able to work through on your own, and there are quite a few group members who will offer advice and suggestions. I'd recommend that you start by providing some more info about exactly where you stand, and how you got there. And maybe answering a few questions: Have you done any further checks on the rig? Do you recall how many "pops" you heard when the "incident" occured? Is the fuse blown? What rig, specifically, are you talking about? What test equipment do you have available for diagnosis?

A real benefit that this group offers is help in self-diagnosis of problems with the Kenwood hybrid rigs.

I have a DD-103 Universal Digital Dial for sale. I have this connected to my TS 520 and it is very accurate and very well built unit. It has been used very little and still has the screen protector attached to the screen. This is the later blue screen.

I have the cable for the TS 520. It can be used on all the TS 520 and the 820. This dial can be used with many different radios and also doubles as a frequency counter.

$120 shipped. I accept pay pal Brian Allen KB4MNG -check out my qrz page.....

Greg-
I can personally recommend OLDHAMDAVE.com. He is close to Asheville NC. I took TS-830s to him and made return trip in 1 day (long day!) form Norfolk VA and you are closer. If you ship radio, probably FEDEX Ground is your best bet, but when it's ready, I recommend a road trip to preserve the integrity of the repair...up to you. I took it down and picked it up because I have minor problem. But since yours may need extensive repair, shipping to him and picking it up from him is the best. Reasonable costs and he gives you breakdown (poor choice of words) of all the repairs he did.

Thanks everybody, but I believe that between the group and myself we can figure this out, if not, a repairman is still a option. What happened to the radio, TS 520S is that I was cleaning the switches and the pots on it with some Detoxit, so I flip it over on it's top, speaker side down, and the large side of the speaker plug, came in contact with the power supply switch, which I traced back to a white wire directly to the rear plug. Not seeing this I plugged the radio in to check it's power supply transformer. The connection at the switch to the speaker plug arced and then I saw a puff of white smoke rise up from the middle of the radio. I heard a pop, which I assume came from the top of the radio, apparently the final amp up there. I just checked the main fuse and it is not blown.
I have the following test equipment on hand, a signal tracer, a Fluke VOM with a capacitior checker, a Heathkit transistor checked, a small tube checker and I can get a "O" scope.
I just need a place to start.
Thank you very much for taking a interest in my delema,
Greg KM4HOY

Topic: 51996 Message: 52003

Hi Greg,

The place to start is to assess the radio.
Besides the pops and smoke you've given us no
other indication of what the problem might be.

Give it a visual inspection - can you see any
blown tracks, caps, resistors, wires etc.
Can you smell anything bad?
Does it turn on?
Are the supplies all correct - you'll have to read the service manual
Does it receive at all - sound and/or S meter indication?
If it receives does it seem to be sensitive enough?
Does the calibrator affect the S meter?

That's probably a good starting point. Leave the transmitter for later.

I'm concerned that you said "apparently the final
amp up there". Firstly, there should be a cover
over the final, if not be really careful there's
900VDC in there. You need to know your radio and
know what each section does - at least roughly.
Know where the power supplies are, know where the
measurement points are. Know where the danger is.

So, start with your eyes, your nose, a VOM and
the service manual. Make notes of your findings and report back to the group.

Regards

Lou

There's a kit that includes the cable and both male plugs that's being sold on eBay for $16.50 plus $4.99 shipping under eBay ad #271852719016

Go to eBay and in the search text box paste the ad number 271852719016 in the text box then click search. The ad will come up.

The ad has a link to assembly instructions in the description section. There's no need for instructions, you simply connect pin 1 on one end to pin 1 on the other end, pin 2 on one end to pin 2 on the other end, and so on. There are no jumpers or cross over connections.

52006. Understanding RF Gain Setting

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-05-07 00:46:11 UTC
From: dgnabq@...
Topic: 52006 Message: 52006

Hi,

I'm a total newbie here with a Kenwood TS830S.

Two questions about the RF Gain knob setting. First there must be a good balance between the amount of RF and Audio gain to minimize noise. At the highest gain for each I would expect the highest noise contribution. Where do you set these knobs for the best performance when tuning across the band to find a conversation of interest or an empty space for CQ.

Second, I notice that when the RF gain is set to maximum in receive and the meter set to RF the S scale reading is minimum but rises when you decrease the RF gain setting. This is counter intuitive to me. Can someone explain.

Many thanks to the Elmers out there.

From: W5RKL
Topic: 52006 Message: 52007

All the meter switch settings are "disabled" in receive. The meter displays ONLY S Unit in receive. The meter switch settings are enabled in transmit ONLY.

The RF gain control varies the bias to the RF and IF amplifier stages which will result in a change in the S meter indication. Rotating the RF gain control CCW will cause the meter to rise above zero. If the RF gain control is rotated fully CCW the meter will rise and peg fully to the right. Rotating the RF gain control CW will cause the meter to fall back towards zero. Rotating the RF gain control fully CW will cause the meter to drop to zero. This is all normal. The best setting of the RF gain control is fully CW. Rotate the volume control to control the audio heard in the speaker. Setting the RF gain fully CW provides maximum receiver gain. If pulsating noise such as ignition or power line arcing noise is heard, turn the Noise Blanker on. The Noise Blanker switch is located on the top left on the front panel labeled "NB". The switch is a Push in for ON and Push Out for OFF. All of the TS-830S control both front and back are discussed in the TS-830S operator's manual.

You did not specify whether you have the TS-830 operator's manual but you did say you were a "total newbie". Therefore, if you do not have the TS-830S operator's manual then I highly recommend you download it. You can download the operator's manual from my website
W5RKL
then click on the "Manuals and Documents" link at the top of the page. When the page comes up, scroll down and click on Kenwood manuals item number "16". The manual will download to your computer free. Once the manual's downloaded, I recommend spending time reading the entire manual. Do not attempt to transmit until you are completely familiar with how to operate the transmitters. The TS-830S requires the transmitter to be tuned properly into a proper load (antenna). The TS-830S is not a "turn on, tune in a signal, and start transmitting" type of radio. The operator must spend time learning how to operate the radio and how to properly use the controls.

The "good balance" depends on the band and band conditions and your ear. You are in the drivers seat.

On 80 meters when copying strong 30 or 40 over QSO you can simply back the RF gain pot down to any level you want for comfortable listening.

If you are trying to copy very weak signal below the AGC threshold simply turn the AGC off and ride the RF gain pot.

AGC Slow is used for SSB and AGC Fast is normally used for CW copy. Some folks run all the time with the AGC off and use the RF Gain pot. Most run with the RF gain pot full CW.

The RF gain pot controls the dc servo voltage to Gate 2 of the gain controlled stages and devices (dual gate mosfets in the RF and IF stages). These devices have a dc bias voltage applied to Gate 1 that sets the operating point on the load line. That bias is turned on and off in RX and TX modes. In a simplistic way can think of these devices as Tetrode tubes.

RF gain pot takes the RF-1 voltage and feeds it thru a 2.2 meg resistor making the AGC bus (or rail) a high impedance power supply. The AGC bus along with differing RC time constants controls the gain of the RF amp and IF Amps dual gate mosfets with differing attack and decay times.

AGC threshold on a well aligned TS830 will be approx -115dBm or 0.40uv. That is the signal level where the dc servo voltage (3.6vdc) just starts down and the S-meter just starts to move up scale. For an S9 indication you need a -73dBm or 50uv signal at the SO-239 connector. OR you need to reduce the RF gain pot until the AGC servo voltage reduces from 3.6vdc to approx 2.0vdc.

The S meter is a FET based reverse reading voltmeter that constantly monitors the AGC bus voltage. When the bus voltage is pulled down by the AGC detector diodes biasing on the AGC amp transistor due to seeing strong on air signal or by you turning the RF gain pot CCW the S meter moves up scale. This is why some folks say its operation is counter-intuitive. Makes no sense to them when you turn the RF gain down that the S meter would move up scale. Have to remember that what the S meter shows you is that the AGC bus voltage is going lower (down from its 3.6vdc reference level) in response to a strong signal and the gain of the RF and IF stages is being reduced. The stronger the signal the lower the AGC bus voltage (dc servo or control voltage to the mosfets) and the higher the S meter deflects up scale.

So you need to experiment with the AGC switch settings and RG gain pot settings for differing band and signal conditions. Simplest operation is to leave RF gain pot full CW, but absolutely no reason you have to do that for all receive situations. KW gave you the controls so use them. Cant hurt anything.

By proper use of the controls you can have very comfortable arm chair copy with your scheduled QSOs on 40 and 80. Dont worry about having a standing S meter indication.

Terry K9TW

52011. 830S AF board loose components

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-05-07 11:43:23 UTC
From: DavidN
Topic: 52011 Message: 52011

Hi guys, my first post. Bought my 830S on Ebay last week. Thought you might be interested in two problems I found on the AF board while investigating a RIT problem.

Firstly, the screw holding the PCB diagonally opposite the relay was pretty loose - it's the one with the black wire to a solder tag on it. I'm not sure it was affecting the set too much as the black wire goes to TPG.

More importantly was Q34, a voltage reg., not being fully bolted to the heat sink. The bolt had a splash of green paint on, presumably from the factory so many eons ago :) , but the nut and bolt just weren't tightened up, so poor old Q34 was away from the heat sink. It needed a good half turn to tighten it to the heatsink fully. I guess it was getting some heatsinking from the bolt it was touching, but even so it's good to know it's now in situ as designed :)

Hope this helps someone, more on the RIT problem another time :)

Regards, David G4TUP.

52012. vtvm with low input capacity

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-05-07 08:38:25 UTC
From: Martin Jangowski
Topic: 52012 Message: 52012

Hi folks,

the service manual of TS-520 and TS-830s states you need a RF VTVM with 1MOhm or more and 3pf input capacity or less.

I'm looking for such a beast, but am unable to find one (even when looking at things with big names like R&S, Agilent/HP etc.). Most have input capacities around 20pf and about 10-12pf with a 1:10 probe. Most scope inputs are in the same neighborhood. The next problem is the usable frequency range... most VTVMs normal human beings can afford have less than 10Mhz upper frequency limit... not quite enough for some measurements.

What kind of VTVM is useable and affordable?

Martin DB2MJ

52013. Re: [TS-520_820_530_830] vtvm with low input capacity

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-05-07 16:00:56 UTC
From: Mike W5RKL
Topic: 52012 Message: 52013

The typical VTVM impedance has a "10Meg" ohm input impedance. The DC probe, when connected to the VTVM, increases the impedance to 11meg. The DC probe has a 1Meg resistor in series with the probe's tip and the input to the VTVM. The AC/ohms probe does not have a series resistor, the probe is straight through resulting in a 10meg input impedance when measuring AC voltages.

The "RF VTVM" is nothing more than a typical VTVM with an "RF Probe" connected to the VTVM instead of the AC/Ohms or DC probe connected to the VTVM.

A typical VTVM can be one of the following:

Heathkit:
V7A
IM-13
IM-18
IM-5228

Knightkit:
KG-620
KG-625

Eico
222
232
249

One important point to remember is, a VTVM with either the DC probe or RF probe connected, will have an affect on the circuit under test. Affects can range from an oscillator simply stop oscillating when the VTVM is connected to the oscillator or the ALC or AGC buss levels will decrease. These issues must be taken into consideration when using a VTVM around sensitive circuits.

There are a couple of popular RF probes such as the Heathkit 309C (single diode RF probe) and the PK-3 (3 diode RF probe). Quite often these RF probes are difficult to find. However, home made RF probes are very simple to build. I built one using small diameter PVC pipe with end caps. I used NTE109 diodes in place of the difficult to fine diodes Heathkit used, the 1N191. I went with the NTE109 because I had them in stock. The RF probe has the same RF level specifications as the Heathkit PK3. There is very little, if any, difference in RF measurements when using the home made RF probe when compared with the Heathkit PK3 RF probe.

I should have mentioned that I have a picture of my home made RF probe
on my website

www.w5rkl.com

Click on the Equipment Photos link at the top of the page.

When comparing the home made RF probe to the Heathkit PK3 RF probe, I
used an N3ZI DDS VFO as the RF source.

Martin:

They are not talking about a RF probe and VTVM in Item 2 of the required test equipment. The clue to you is the 10mv range and 50mhz frequency range.

Item 1 on the list is a standard 11 meg VTVM. You cant measure the TIF signal for example with your RF probe and VTVM. You need a good O-scope or RF millivolt meter for that measurement. The diode barrier voltage of standard RF probes with germanium signal diodes limits how low a signal you can measure. Usually around 250 mv. You may get some meter deflection lower than that but wont read it very accurately.

Item 2 that you are asking about is a RF Millivolt Meter.

Some good ones include any of the Boontons like the 92E. You must use the Boonton probes with their meters. You can also use a HP-410C and its AC probe that uses a vacuum tube diode. RF millivolt meters are not cheap and often are sold without the probes. From time to time you can find a Motorola or Millivac unit and they typically are a little cheaper than the Boonton but work very well. The Motorola is made by Boonton for them. Ballantine makes another but not as commonly available. Absent an RF Millivolt meter you can use a good O-scope to take all the RF voltages in the radio.

You can just add a RF probe to the VTVM listed in Item 1, but realize limitations on measuring low voltages and of course loading effects on some circuits. I would say you can use an RF probe and 11meg VTVM for about 90% of the alignment steps and/or any troubleshooting you need to perform. I recommend you start with that as first piece of test gear and worry about stepping up to RF Millivolt meter after you get Freq Counter,good RF sig gen, and O-scope.

I would not be without my Boonton 92E and 92EA RF Millivolt meters and probes and 40db attenuators for the service work that I perform. I also have a good digital 100 mhz scope with digital filters so I can look at and measure a stable TIF signal. Lastly I use my HP-410C for any AGC or ALC work as it has 100 meg input impedance. The busses dont know the meter is connected.

I also have a Heath IM-18 and 309C and PK-3 probes and use it all the time to perform tasks like neutralization and carrier balance and carrier suppression. I do that because cheap to replace signal diodes if I make a mistake. Not so cheap to replace Boonton RF probes.

Thanks for the explanation. There is one thing I don't understand: a RF probe is nothing but a resistor, a capacitor and a diode. The capacitor is loaded via the dide and the resistor and the VTM measures the voltage over it, 1/2 Vpp of the rf voltage at the test point. The diode has a threshold voltage (about 0.2-0.3V for schottky and 0.7V for silicon). So it should be impossible to measure voltages less than this threshold voltage (and the measured voltage is Vthr. too low)?

Martin

Setting all the technical explanations aside, my simple way of understanding the RF Gain/S Meter relationship is that, as you reduce the RF Gain, you're increasing the threshold a signal needs in order to be heard. Although I may not be totally technically correct, as the S-Meter needle moves up as RF Gain is reduced, for all practical purposes, you can think of the new "zero" location as indicative of the new higher threshold in terms of S units.

If the new "minimum" needle location is S-3 instead of zero, I would only expect to only hear signals with a strength of approximately S-3 and higher. Another way of thinking about it is, if your noise floor is S-3, reducing RF gain so that the needle moves to just above S-3, will block out the portion of the noise (and other signals) that is S-3.

I usually leave the RF gain at full clockwise unlless there is a lot of background noise like lightning crashes on the lower freq bands.Then reducing the setting reduces the volume of the noise between dahs and dits from the station I am copying. My radio is Ham Radio...CW is Real Radio

Dave,As you reduce the RF gain the sensitivity of the receiver drops and the S meter is showing you rioughly the level of signal that must be reached by incoming stations, to make the AGC start to level the audio output. If there is S-0 noise you can keep the audio volume set at 1/3 clockwise, RF gain at maximum, and with the agc on the strongest signals will NOT blast you when you tune across them ! You still will hear the weak ones just fine.That is the "balance" you are looking for, I hope. My radio is Ham Radio...CW is Real Radio

  Hi,
I'm a total newbie here with a Kenwood TS830S. questions about the RF Gain knob setting.
 Second, I notice that when the RF gain is set to maximum in receive and the meter set to RF the S scale reading is minimum but rises when you decrease the RF gain setting. This is counter intuitive to me. Can someone explain.
Many thanks to the Elmers out there.

In noisy (summer static conditions) on 160, 80 and 40, I will back the RF gain completely off, turn of the AGC and set the AF gain to max. Then I will use the RF gain as the "volume control" advancing it to make the station audible. You need to be careful, since there is no AGC, a sudden loud station can blow you across the room. I do find this does mitigate the noise.

Thanks Mike,

All good information. I have been very fortunate in getting a one owner TS830s including the original manual. I have read it twice now but not everything sticks even then. Mostly I was confused by the counter intuitive motion of the S meter as the RF gain is reduced.

With the help of information here and some other internet research I have been able to properly tune up the rig and make a few QSOs. But I have much too learn. One reason I chose an older hybrid rig was to force a better understanding the inner workings of the RF stages.

Thanks again for your help.

Thanks Terry.

That's very helpful in understanding what I see as I change the RF gain and also how to better utilize the AGC controls. I knew the HF world would require much more learning so thanks for the information. Skill and understanding will take time. I'm still struggling to understand how propagation changes through the day and seasons. The noise level and how to deal with it is part of that for me. After 20 years flying in AF fighters and using UHF (either it worked perfectly or it didn't at all) the HF bands are a challenge.

Dave,

Check the "HEATER" switch, it may be turned OFF. Turn the HEATER switch ON then check the rear panel "SG" switch to ensure it's in the "ON" position then check for 60ma IP current in USB or LSB transmit again.

Hi Dave,

Okay, will do.

Those members who post questions referring problems with their KW hybrid, please include the Model of KW hybrid in the subject line and/or post's text. It makes it much easier for someone to provide help if they know what model of KW hybrid you are referring to.

If you do not know what model of KW hybrid you have, then simply look below the transceiver's VFO knob, the model number is in large letters/numbers.

Rich,
Congrats on obtaining a great rig. Just as in other things..some guys like one thing..some guys like something else...and it's no different as far switch/contact cleaners go. Most times, DeOxit, made by CAIG, is a fine product to use. The are several strengths...the lower strength works fine for me. There is a spray and a liquid...you choose which one you want...I use the spray and have had no problems with "over spray." Also, get a can or two of "canned air" ...aka "air duster," you can find it at WalMart,and computer/business stores. This is used to blow off the junk that the DeOxit dissolves. I would recommend loosening and retightening ALL of the screws on all of the boards...especially the AF-AVR board. There is a "fix" that involves making a jumper wire from the "G"(ground) post on the AF-AVR to the screw in the nearest corner.

I will not hazard a guess about your power output problem...as a bit more info is needed...say... under what conditions does the power drop off...what is is HV(high voltage) reading with the rig at idle...and properly tuned up..and in transmit? If you have only about 400VDC under transmit conditions...STOP! as you more than likely have at least one bad HV capacitor...(not uncommon)...continuing to operate like this can and will cause other problems that you just don't want to get into right now.
Give as much detail as possible to help us help you in figuring out your problem(s)
Oh, you don't have to remove the band switch wafers for cleaning...unless you really want too..and the DeOxit can be used on all the other switches and pots too.

Hi all,

My name is Chris and I am a new member to the group. I have recently acquired a great work ts-520se and am loving it. The only issue with my station is my MC-50 desk mic works intermittently. I checked all the soldered connections and grounds and what I found was 1. There's only a blue wire connected to one lead on the on off switch and the mic works in either position. 2. There's a red wire coming from the connector that looks cut and not connected to anything right next to the switch leads. 3. It will work fine for long rag chews over and hour long but the moment I change bands and retune the radio it stops functioning. 4. If I tap on the screen where you talk into, it will start working again. I consider myself adept enough at soldering and able to make necessary repairs. Thanks for anyone who has any information!

Topic: 52035 Message: 52036

Chris,

From your description I suspect you do not have the manual and schematic for the mic so I attached it. The reflector will strip the attachment so I also sent it to your personal address. Since you can see the wires I am assuming you knew how to disassemble the mic but I also attached a description of that process.

The blue wire (connector pin 2) and red wire (connector pin 4) are both connected to the on/off (PTT) slide switch. That switch is only used if you remove the mic from the MC-50 base unit and connect the coiled cord directly to the mic. When the mic is connected to the base the slide switch on the mic is not connected to the PTT circuit. Normally, you are using the PTT switch that is part of the base unit so you would never know if the switch in the mic has failed. This explanation answers your points 1 and 2.

As for points 3 and 4, it sounds like an intermittent connection caused by a broken wire on the mic element or other wire in the mic/base unit, a dirty PTT switch contact, or a dirty relay contact in the rig. Do you have another mic you could try so you can determine if the problem is with the mic or the rig? If you do not have another mic, the next time it doesn't work try clicking the PTT switch on the base unit a couple times and do not tap on the mic screen. If it starts working then I would suspect an intermittent in the base unit (wirer/switch) or a dirty relay contact in the rig.

You didn't specify what you meant by "stops functioning". Does the PTT not work or does the PTT work and you just don't have mic audio? Since you have a broken wire on the mic slide switch, a condition I have never seen, I would disassemble the base unit and cables to check all of the wiring connections and test the continuity of the PTT switch. This is easier than working on the relay in the rig so I would start the easy items first.

Keep the reflector posted on what you find. Good luck!

Disassembling the Kenwood MC-50 and MC-60 Microphones

The mic head and the connector are both screwed then glued into the body. You need to soften the glue then unscrew the parts counter clockwise looking at the head or the connector depending on which end you are trying to remove. In order to separate the head and connector from the body for placement of the body in the cleaning unit you will need to unsolder the mic head and remove the switch. Make note of the wiring before unsoldering any wires.

To disassemble the MC-50 (or MC-60) mic wrap the microphone body in an old cotton shirt/cloth/towel to keep from burning your hands. Do not use any tools to grab the mic body or parts or you will damage them! Using a heat gun or hair dryer heat the joint between the head of the mic and the body or between connector and the body. Keep trying to unscrew the head or the connector (counter clockwise looking down on the mic head or connector). The mic head or connector will unscrew after sufficient heat is applied. Again, do not use any tools to hold the mic body or parts!

The following link has several pictures showing how to disassemble the MC-50 microphone for cleaning:
http://s261.photobucket.com/user/ai4wm/library/Cleaning%20Kenwood%20MC-50%20Microphone?sort=6&page=1

Click on the "Story" block at the top right of the pictures, directly below all the "Twitter and Facebook icons".
This will show numerous pictures of the steps taken plus some text of what the pictures show.

Ken,

Thanks, that is exactly the information I am looking for! It definitely looks like somebody messed with the mic because the wires are completely twisted as if the element was being turned repeatedly, I'll keep the group posted on what I find!

52038. Hybrid Net Update (May 10, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-05-10 21:49:10 UTC
From: Mark Gilger
Topic: 52038 Message: 52038

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by me, WB0IQK. There
were 25 stations checking in under good band conditions.

We had the following number of radios checking in.

3 running TS-520(x)
5 running TS-530(x)
3 running TS-820(x)
7 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running my TS-830S + Drake L-4B amplifier.

The Sunday net was run by me, WB0IQK. There were
11 stations checking in under poor band
conditions. We had the following number of radios checking in.

3 running TS-520(x)
0 running TS-530(x)
1 running TS-820(x)
3 running TS-830S
1 running TS-510
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-940S + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome

as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total = 142, Sunday☐s total = 88
December 2014, Saturday☐s net total = 92, Sunday☐s total = 86
January 2015, Saturday☐s net total = 110, Sunday☐s total = 84
February 2015, Saturday☐s net total = 103, Sunday☐s total = 98
March 2015, Saturday☐s net total =80, Sunday☐s total = 51
April 2015, Saturday☐s net total = 59, Sunday☐s total = 29
May 2015, Saturday☐s net total = 43, Sunday☐s total = 23 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

From: oh3gd@...
Topic: 50055 Message: 52039

For your information:

Found the reason for the display problem. As surprising it might sound, it was about a short circuit between R1 (in 5V-AVR UNIT) and heat sink over the resistor. The contact was not steady, but was loading 14 V dc supply time to time so that the voltage was dropped suddenly. The resistor is in a cemamic case and the heat sink loacated over it. Sounds like a good isolation, but wasn´t that any longer. I suppose that the previous owner has dropped something liquid dirt from cooling holes, looked like a dry sauce...

Look at the heat sink mounting very carefully. Pretty common for it to move around easily.

Heat sink is mounted on top of two long hex standoffs and is in near contact with the power transformer metal shell. If the 3 lead wires from the Regulator that is mounted on the heat sink are not cut off exactly flush any motion of the heat sink can short the sharp stub ends of the regulator leads to the transformer shell.

I remove the heat sink (2 screws) and tighten both of the standoffs with hex nut driver. While the heat sink is off inspect the leads from the regulator to make sure they are not protruding from the PC board. If so, cut them off flush. Can also place some insulating "fish paper" in the small gap between the PC board and the power transformer shell.

Fish paper can still be purchased on Ebay.

Hi Group,

This is a new-to-me rig, I didn't really need it but the price was unbelievable so I jumped on it. It has a few issues that I've been able to work out, but I have a question about this one.

The inner dial on the VFO is off. It starts out ok but increments too soon. As I'm spinning it goes from 40,50,60,170,180,190,100,110,120,130,140,150,160,270,280,290,200 etc.

I took the VFO out to see if I could just slip that inner disc back, but they both appear to be on the same gear. I'm not sure how this issue could have started unless the previous owner took it apart and reassembled it wrong.

Any ideas? Do I need to take that outer dial apart to fix this, or am I overlooking something simple?

OK-- Maybe I should not have called the 3 leads from the 3-terminal 5 vdc regulator package "lead wires". I am not talking about any "wires" making contact with the transformer shell.

This is a TO-220 package with 3 "stabs" or " pins" ie Collector, Base, Emitter.

These flat stabs like all power transistors in this style package protrude thru the PC board and are soldered at pads on the foil side and the excess stabs are cut off. Sometimes they are cut off long and are not flush cut and leave a sharp tip that will contact the transformer shell and rub and penetrate the black paint and short to it.

If you cant find "fish paper" I suppose couple of layers of black plastic electrical tape (scotch 33) could be affixed to the transformer at that location. I would also file flat any sharp points on the three stabs so they cant penetrate the tape.

So again you are not looking for any leads or wires.

Tyler,
Two things could have happened..but it's a moot point.....somehow the "outer dial"..has been messed with and got out of sync. The gearing of the VFO is pretty neat when you watch it work. I can give some some detailed instructions later, but in the mean time...set the VFO to approx XX.200MHz, remove the knob and the flat plastic piece right behind it. Loosen the two small screws that hold the outer dial to the shaft..slide dial towards you.. You will notice that the inner dial has groupings of numbers the correspond to the first digit of the frequency. You should also be able to look through the small hole in this inner dial and see a screw behind it..don't worry about this screw...this hole just indicates the the dial is approx. where you want it. Using the inner dial as a guide center the square hole of the outer dial...over a "2" on the inner dial...a "2" should be almost at the 12 o'clock position..snug up one screw..and rotate the VFO shaft to see if the inner and outer dial are now in sync. It may take you a couple of tries.
If after numerous tries, it's still out of sync...then it's possible that the "backlash" spring is broken/missing.

Thank you both for the help! It was a bit tricky but I was able to get it lined up properly.

The previous owner must have disassembled and reassembled this thing because it was off 90+ degrees. All of the screws were tight (maybe even too tight). Finding the set screw that keeps the inner dial tight to the shaft was the key, then I was able to rotate the dial so the "5" was at 1 o'clock like Mike suggested.

All is well now, thanks again.

Terry, thanks for responding. Yeap, the problem was in the resistor (R1) in this case indeed. It seems that there has been dirt which has becomen conductive. Wasn´t able to notice the contact first (actually, not for a long time in fact), but after several times soldering wires off from PCB, the problem was able to see clearly. When the resistor was removed with surrounding heat heat sink (or should I say copper heat transition pads to the larger aluminium heat sink) the resistor was found faulty and short circuited to the copper pads. So far everything seem to be ok after replacing the resistor.

Yes, you are right about that the length of the regulator wires might cause problems too, but those seemed to been cut short and spaced far enough from the heat sink.

52050. Almost "new in box" TS-520 and a few questions

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-05-12 06:16:31 UTC
From: Martin Jangowski
Topic: 52050 Message: 52050

Hi folks,

this weekend I got hold of a almost "new in box" TS-520 from the original owner. The rig was bought for a school project, but saw almost no use during the years.

Of course, first thing I did was looking inside. Everything is clean and shiny, and the finals are the original S2001A tubes. The first test was very promising: clean and bright audio (identical sound in USB and LSB), the scale was spot on (no digital counter in a TS-520), signals are easy readable, no difference to my TS-830.

Tuning the TX required reading the manual (it's true: "if all else fails, read the instructions"). There is a grey "H.SW" switch on the front side that needs to be switched on to get plate voltage. The SG switch on the back side was off, leading to no current when trying to set idling current. Finally, I could easily set the bias voltage for the needed 60mA idle current with the pot on the left side.

A big surprise came when tuning the finals. This rig has lots of muscle! I did the usual adjusting the drive in "TUNE"-mode, dipped the plate, and started the "load" and "plate" game for maximum output at the power meter (using a dummy load, of course). Surprise: I got about 140W on 14.175! Looking for the plate current, I saw it was very high (at about 300mA), so I reduced it with the load control until it showed the recommended 225mA. Still 130W. Wow! The HV caps are of course original, I have about 900V plate voltage and only minimal drop when putting it to send in cw for a few seconds. I like this...

This leads to a few questions: my TS-830 is absolutely unable to get this kind of output. It peaks at about 70-80W at 14.175, and I'm unable to get (much) more than about 200mA Ip. When getting the TS-830, I replaced the screen and cathode Rs, the HV caps and the choke and the two caps in the finals cage (all parts from Ken K4EAA). I didn't replace any tubes. I can get full meter swing in "TUNE" and "ALC" mode on all bands with the "CAR" control (till pegging on the right side). According to several posts here in this group, this means that I have a working driver tube. Plate voltage is about 900V (measured with a high quality DMM), the cathode Rs measure 5 Ohms (being new, this is expected...).

The next step will be swapping the obviously perfect S2001A tubes into the TS-830 and see if this will bring roughly the same output as the TS-520. If not, I'm going to cry for help ;-)

Martin:

Interesting experiment. Let us know how it goes. I has S2001A's in my TS-520 when I first got it. I'm not sure what's in there now, since I tried swapping tubes as well to see what I got in terms of output.

Of, course you'll have to neutralize the final when you put the S2001A's in the TS-830. And you may as well try swapping out the 12BY7A as well.

Are those currently 6146B's in the TS-830?

I would not like to see 140 watts or 130 watts output on any TS520 especially mine given that it is rated at 160 watts DC input power and not 180 watts. One sure way to attain that level is to QRO the rig.

Under the CW operation section of your owners manual you will see that recommended plate current is approximately 200ma and not 225ma. Of course if you load quickly to 225ma and run only short duty cycle modes like SSB and CW you should not measurably shorten the life of tubes or power supply by loading to 225ma. Loading radio to that level of plate current instead of 200ma will make no difference on the receiving end.

Your TS830 is of course not operating to design on 20 meters. If 6146 Anode and Screen grid voltage and tube emission are all normal what is the RF drive level? Should be in the high 40s to low 50s rms rf volts.

RF board bandswitch contacts are the weak link in this radio.

May I make a light-hearted suggestion to the moderators here?

At the top of the front page, can we include a question..such as:

"Is the SG switch in the proper position?"

I love reading the posts with queries and subsequent answers, and have learned more HERE than you could ever get from just reading the *&%^(* manuals. However, after years of following the posts, it does seem that one question would solve at least a quarter of all issues.

Now, can someone spell out where to find the planet's "SG Switch"???

Hello groups,
I am on4agy and licentiate sinds 1987, i have the full line of the TS830S without the scope.A very good set.The antenne is a G5RV home made.
I have also a TS 450S and a TS 820 as well.Problem : for the TS 820 : the last days when y stop the transmission en go tho revieve , there is a few seconds time before y can listen, it is the same with cw.
So can someone help me ?
Thanks in advance,
Pierre/ON4AGY

Check the "Relay Unit" (T/R relay). Check VOX settings, too, just to be certain.

John,
Are you referring to the group "Home Page?" So, a rig is new to you...and "it won't do this or that"...or, "I just moved the rig so I could clean the shack...and now I can't get any power out...where should I look?" If the rig is new to you..even if not...do you have the proper owner/operators manual? If no, why not? All Kenwood hybrid operators and service manuals are available from several sources that are associated with this group...along with schematics(FREE)...n6wk"dot"com & w5rkl"dot"com are just two. Many difficulties can be solved by reading the appropriate owner/operators manual. Please don't get me wrong, this group will go to great lengths to help solve a problem...but some things are just so basic. You can spend more time writing a post and waiting for an answer that to look through the correct manual.
For the every group member, and especially new ones: you can go to the group home page and search "conversations" regarding your problem. I can say with 95% certainty, that someone else has already had your problem...and a solution found. Also, the "files" area has lots of good info too.
Here endeth the sermon.

From memory. On SSB check the time constants around the T/R electronic switching. Mine had a similar problem and it was caused by too large an electrolytic that made the switch over time too long.

I switch the Noise Blanking on and off on my TS-520 and there is no difference at all. Is that typical? I check on all bands and it is the same no difference. Do any of you hear any difference between the NB on and off? Is there a way to help ensure that I would typically hear a difference?

I can go ahead and trouble shoot from the switch onward, but I thought I would ask first.

On the off chance that it is not working, is there a common problem with them?

Many thanks,

Larry Forman AJ6G

Hi Larry,

It depends on the kind of noise you want it to
blank. Impulse noise with steep rise times is
where the Kenwood noise blanker works best. Mine
works fine stopping electric fence noise from surrounding farms.

Go to page 8 in the TS-520S operator's manual, Circuit Description section that discusses the Noise Blanker. The Noise Blanker works on "pulse type noise" such as arcing from power lines and arcing from engine ignitions systems. The Noise Blanker will not work on atmospheric noise, lightning static, and other non-pulsating noises.

Larry,
The noise blanker is designed to reduce pulse type noise...like spark plugs...etc...you can do a quick test by using a motor that uses brushes....a variable speed drill motor...blender..or a hair dryer. Fire up the noise maker...and turn on the "NB" You may not get the noise to go totally away..

Thanks, Joe, for your reply.

My apologies to all who did not see my "sarcasm" light flashing.

The listed "help" topics, like "read the manual" are most appreciated. Having the tech manuals as well as operating manuals in hand are a necessity with these "older" rigs, especially for those new to the hobby or for those who are working with a recent acquisition.

The SG switch comment though, should also go along with standard reminders such as "is the rig plugged in, and "is the power switch on?" We DO get wrapped up in these rigs, sometimes narrow our focus, and very often forget some of the basics.

No offense intended to ANYONE reading these posts. This group is THE place to get answers, usually quickly, to many questions about the Kenwood hybrids. Many thanks to all the owners and contributors here.

Humbly yours...
John/N7IQV

52063. TS-830S Digital display does not tune with tuning with tuning dial

Hello Everybody,

I am wondering if anybody has run into this situation.

I purchased a TS-830S Gold version on Ebay.

The display does not change while adjusting the tuning dial.

Also, the display reads 500KHz below the band base frequency (Ex: For 7.0MHz, the display reads 6.5MHz) Adjusting the tuning dials does change frequency as read from the analog dial.

Thank you and 73

Cedric

OK, all that makes sense. I will fire up a noise maker or two and test it out. Now that I understand what typical noise it blanks, it just might be the relatively electrically quiet neighborhood I live in. It is in the suburbs south of Sacramento, located along the Sacramento River. All the utilities are located underground, which should likely help. Most of the cars in the neighborhood are modern, except for in our garage (my wife's 1954 Nash Metropolitan convertible) and our driveway (1970 Ultravan RV with 1970 Olds Toronado powertrain transplant).

Thanks for all the helpful suggestions.

John, No worries. I did observe a slight flashing of the sarcasm light. Yahoo is the entity that governs how much info and where you can put it. It's not always as easy as one might think. As the electronic techs onboard ship would always start out with: "is the on/off switch in the "on" position?" Many of use have had the duh moment...most recently...I had a problem with the frequency not changing when the VFO knob was turned..oh great what now...I had inadvertantly hit the "DH" (disply hold) button. Anyway..no offence taken....enjoy your time with us 73 Joe

Hi Craig,

Besides the original Kenwood literature this is
the best place to get information on how to wire microphones.

http://homepage.ntlworld.com/rg4wpw/date.html

As for your problem you haven't given us much to
go on. Sorry if the questions are really simple
but you say you're a newbie so best to start at the beginning.

If you unplug your microphone and flip the send
switch up momentarily does the meter behave the
same way? If the radio behaves differently when
you use the send switch to when you use the mic
button then you may still have a wiring problem
in the mic. If it behaves the same then your wiring is probably ok.

Have you have downloaded and read the operators
manual and do you understand how to set up the
radio? You can find the manuals here http://www.n6wk.com/kenwood/

Tell us how you have your radio set up especially
the mode switch? When you follow the tune-up guide what do you get?

Regards

Lou

> is the RF drive level? Should be in the high 40s to low 50s rms rf
> voltrys.

I measured the DC levels, they are ok (+/- 2% of ref. values). One voltage is a little lower, G1 voltages are -102V/-57V (RX/TX, should be -101V/-62V). TX @ 14.175, CW, max. output (about 70W). I checked the 6146Bs and the driver tube with the TS-520, full output (130W@225mA Ip, >100W@200mA Ip).

Modulation voltage is about 70Vpp @G1, no visible voltage loss from DRV thru C1/PS1,2 (measured with TEK 465B/6105 probe). 50Vrms is 140Vpp... could be the culprit.

> RF board bandswitch contacts are the weak link in this radio.

When changing the caps, I removed all wavers (except these in the HV cage), cleaned them with a ultrasonic cleaner and measured contact resistance of every contact... all measured <20 miliOhm. I haven't measured any voltages at the driver tube (how to do this without removing the RF board?)

The TS-830S has a negative feedback loop from the output to the driver tube. Too much negative feedback = low output. I don't quite understand how this NFB-loop is dimensioned, which parts are used to generate the correct amount of feedback?

Martin:

I have a hard time understanding what you are reporting. It sounds like you are saying you removed all 7 of the reddish/brown vertical bandswitch wafer boards and cleaned and measured all the contacts. If so assuming you got them all soldered back in properly without any lifted pads or cold solder joints then bad band switch contacts should not be your problem.

I assume that you are seeing 70 to 80 watts output on all bands? If on just one or two bands often the problem is bad bandswitch contacts on the RF board wafers (not on the S22 switch in the PA Cage). If low output on all bands then not likely bad bandswitch contacts. Can be bad RF Plate Choke and/or Plate block and/or RF bypass capacitor in PA cage. If just low output on 18 mhz then often bad Driver tube Plate choke L36. If intermittent RF drive and RF output then can be bad solder connections at the Driver tube socket. Often can see this by pressing and pulling on the tube shield while key down.

If you are saying that you measured the RF drive level at Control grids (Pin 5) of 6146 finals and see 70 volts P-P then that is very low. Should see approx 140v P-P. I assume you are using 10x probe. Your scope probe may be detuning the LC circuit so you may have to peak the Drive control to see if you can improve the reading. Scope probe should not detune to this low a level.

Look at the TX Level Diagram in the Service Manual. These are taken after rig is loaded to full output at approx 14.2mhz and then shut off the SG switch and measure the RF drive levels with your O-scope, RF probe/VTVM, or RF Millivolt meter. All three instruments will produce slightly different readings due to varying input impedance.

Seldom have loss of TIF signal so I would move past that point for starters.

Look at TP-4 which is the output of the TX Mixer. This is first place in the scheme where you will have the actual transmit RF frequency. You should see approx 2 rms or 5.7 P-P rf volts drive. This is what is coupled to the Driver tube control grid. If low here make sure you have approx 1.0 volts of VCO signal which is the LO for the TX mixer.

At the Plate of the Driver tube should see approx 66 rms or 187 P-P (make sure your scope probe can handle the Driver tube dc anode voltage)

I use a Pomona test socket under the Driver tube for testing but if careful can get on the tube socket pins if you need to. If output low on all bands and you tried another good 12BY7A tube then I would measure the Anode and SG voltages (especially SG). If very low look at 210A and R36/R37 divider.

I would not worry about the RF negative feedback circuit. It almost never causes a problem. It is essentially feedback around 2 stages. The Finals and the Driver. Only time it comes into play is when you overmodulate or if you try to load into a very high impedance or open feedline which then presents a very high VSWR. It couples rf output from the tank circuit

back to the cathode of the Driver tube via a 3pf 3kv cap. You can see the white wire from the feedthru on the PA cage front panel to the base area of the Driver tube. This coupled back RF reduces the gain of the Driver tube to reduce adjacent frequency splatter. Other piece is that the Driver tube must be neutralized in this scheme and you can see 1pf capacitor that is connected between VC-3 and VC-2 air variable capacitors.

You can test the RF negative feedback circuit by coupling your scope on the white wire feedthru at PA cage with rig loaded to 100 watts in to dummy load. Set mic gain to approx 1200. Speak into mic with a protracted "Threee-Threee" or "Fiveee -Fiveee" and you should see approx 800mv to 1000mv rms rf volts. If you have a good Audio gen set it for 1200hz @ 7mv and input this into the mic jack. Should then see steady 1000mv of feedback and ALC indication at the far right hand end of the black printed meter scale. Again I would not worry about RF negative feedback circuit until you prove that your have normal TX Level Diagram readings.

Martin I am very busy at this time and should not be engaging here. Besides bench work get lots of off list requests for help. I may not be able to give you timely feedback. I think at this point have pretty much given you what I know about low RF output power. I assume you have checked the MX2P Ant TR relay contacts and made sure that the tinned lead wire from the relay to the center pin of the SO-239 connector inside the PA cage is soldered. Also make sure the soldering at the two parasitic suppressor on top the RF plate choke are not sublimated. OK you now have pretty much everything that I know about low RF output. Just go slow and systematically and be aware of your surroundings when taking readings. Dont want to get shocked or worse.

Martin

One more thing. I forgot that you recapped this radio.

Hopefully you did not place a capacitor in the "C13" position on the Final board?

If you did remove it. C13 is only installed in 830s for the overseas market that run reduced power. C13 shunts portion of normal RF drive to chassis ground.

If you did not install a C13 cap and you have normal DRV level at the Final board and low level at 6146 control grids then you can look at C1 100pf coupling cap, but it seldom fails as it is in series with DC block C29 .01uf cap.

Hi Joe,
We repair 'old' technology radios but live in a high-tech world and
sometimes complain about non-repairable modern devices.
I use a small cheap tablet alongside my 820s.
The tablet touch 'digitizer' screen failed. I tossed it out but then decided
to open it and have a look.
Re-seating the digitizer ribbon cable connector using a drop of DeoxIT-D5
brought it back to life.
Well done DeoxIT! Back to the future...

What do you mean by "funny" crystals? Wrong frequency, in the wrong place? If you have crystals that are about 1MHz off...then someone most likely has done the "CB HACK." There could be other mods also. Check that ALL the wires that come from the transformer, and to rectifier board are all in the correct place, as well as the screen grid resistors. Changing the voltage to the screen grids of the final amplifier tubes is a popular "QRO" mod. which places severe demand on the transformer, final amplifier tubes, plate choke...also for maybe 15-20 watts of more output...which more than likely won't be noticed on the other end. International Crystals in Oklahoma City, OK is a top notch manufacturer and supplier of crystals and can supply what you need. Price of fresh/new ones are going to be about 20-25 bucks a pop, or try Bob Mansker at ke5ftf "at" mail "dot" com. 73 Joe WB7UQU

There are different HET OSC crystal for each HF band. The following list are the individual HET OSC crystals for the TS-520 Models. To determine the model you have, look below the front panel VFO knob, the model will be in large letters/numbers.

The TS-520S and TS-520SE came from the factory with an RCA socket on the rear panel labeled "HET", the TS-520 did not.

To measure the individual band switch selected HET OSC crystal frequencies, connect a frequency counter to the TS-520 RF Unit's TP3 or the rear panel HET socket on the TS-520S and TS-520SE. Cycle the band switch through the HF band settings, making note of each frequency displayed on the frequency counter. Compare the frequencies to the following list. Any differences, especially on the 10 meter band, can indicate a CB hacker's modification which typically requires removing the CB crystal and replacing it with the original 10 meter crystal.

160 meters - 10.695Mhz (TS-520S and TS-520SE ONLY)
80 meters - 12.395Mhz
40 meters - 15.895Mhz
20 meters - 22.895Mhz
15 meters - 29.895Mhz
10 (28.0) - 36.895Mhz
10 (28.5) - 37.395Mhz
10 (29.1) - 37.995Mhz

International Crystals in Oklahoma City, OK, can make new crystals for you (see their website for their 800 number).

You're most likely hearing CB transmissions. My TS-520 was also converted to CB when I got it. I was able to replace my 10m crystals without removing the board, which saved a lot of time and disassembly. It's a little tight but doable (a small hemostat is helpful). The crystals I received from International Crystal had just the right lead spacing for the holes in the PCB.

Fortunately, my 520 didn't appear to have any tweaks other than the crystal substitution. You might want to check out this link for some info:

The Service Manual provides the characteristics for the optional CW filters. YK-88C input and output Z = 600 ohms.

It is not very critical to have exact match and if not terminated the worse you will see is some pass band ripple. It wont effect the filter Fc or bandwidth if not terminated precisely. More common failure is to see the Fc shifted significantly.

Given that your Tracking Gen will be 50 ohms I would try a 470 ohm series source resistor at the end of the filter you select for the input and I would terminate the other end with 470 ohm shunt resistor. Try these values for starters. Some folks use a trim pot at each end and connect the filter in and out to the wipers and the signal in and out to the hot end of trimmer and filter common to cold end of trimmer.

The resistors will introduce insertion loss but your Tracking Gen should be able to compensate for that.

I should probably qualify my remarks to say if you just want to check to make sure not a defective or grossly shifted filter then wouldnt worry too much about precise termination.

In addition to proper resistive pads at input and output a more precise test would also use a test jig with a common ground plane and terminating shunt capacitors. If you terminate with significantly lower resistance Fc will shift downward to some degree and if terminate with significantly higher resistance Fc will shift upward.

One problem you can experience is shifting filter response with hand contact and/or movement of your interconnecting coaxial test leads from the TG output and SA input jacks.

After doing your bench sweep and installing the filter on the IF board you can sweep it again in circuit before re-installing the board.

I understand your desire to make sure you have a good filter before installing in rig, but best test will be how it behaves in circuit in operational setting.

If you come up with a good test jig and methodology I would be interested in learning about it.

Some filter manufacturers data sheets and app notes show the filter test configuration.

I think the I/O termination for the filter is 600 ohms + 10 pf or something near to that. You can get a pretty good view of the filters performance by using a set of min-loss pads to swamp the Z difference. The downside is that the penalty for this min-loss pad is a bite out of the dynamic range (17db per side?) of your analyzer. So if you want to see the ultimate attenuation of the filter alone, you probably need a N2PK or something with massive starting DR. To check the top of the filter response, the min-loss pad is quick, cheap and works well.

Not accommodating the Xj will show the ripple in the filter that’s not likely there in the actual circuit but to test if the filter is working or not, this is a FB method.

Probably a 12:1 ferrite transformer would exhibit the lowest loss. However not very convenient to have to wind various transformers to test all the available optional KW filters.

Simple 2 resistor L-pad calculators are available on line to calculate R1 and R2 just have remember to turn them around. Problem is it will produce non standard values of resistance and as you state a "min-loss pad" with high loss. Using one of these calculators and inputting 600 ohms and 50 ohms arrive at R1 = 574 ohms series resistor and R2 = 52 ohm shunt resistor for approx 17 db loss.

I have played with these L-pads and really not much different than using a single series source resistor at the input and a single shunt load resistor at the output for go-no-go testing of an Ebay purchased filter. I have never seen any original response curves for the factory KW hybrid filters. Would be nice to have them to compare your as found results.

If anyone lacks a Spectrum Analyzer audio spectrum analyzer soft ware (like Spectro-gram) and diode noise generator makes excellent way to see the filter response curve. Only problem is you have to take a chance and install the Ebay purchase and then test.

Lately seeing a rash of TS-820S with bad CW filters. If you set Carrier Osc to filters Fc of 8830.700 as service manual directs will have little or low ALC indication when peaking Drive. Since I cant change the filter response I adjust the carrier oscillator trimmer to bring the oscillator to the filter. Usually results in something around 8830.300 for good ALC indication on 10 meters. Not sure if seeing problems with the crystals or caps aging or both?

Topic: 52086 Message: 52092

thx jeff/terry for the replies. very good...

let me explain the rationale for even asking -
just want to give my used ebay filter a sanity test. I have spectrogram & noise gen as well as a Rigol SA, good set of lab eqpt.

the 500 hz cw filters that I have in the radio now are getting what seems like 20+ db of attenuation killing the receiver for use on cw on the upper bands when in CW.N mode. It does seem to have narrower response, and the 20db is maybe tolerable on a summer night on 80m as one can use some attenuation there anyway! Flip it back to CW.W, and the RX comes back to norm.

It may be the filter, it may not. Since I have never seen one fail or be "bad", I simply don't know what their failure mode is. So I came across one and want to test it before pulling out the board etc and again unsoldering/soldering another one in. Every time I take boards out etc, it adds risk that something else goes wrong from the handling on these older rigs.

Of course I'm curious about response curve, but also primarily for excessive loss. Measuring ultimate stopband/attn isnt primary here. So a little passband ripple because of non-ideal matching isn't a show stopper for my purposes. I'll try the series/shunt resistors for simplicity sake at the point.

what do you guys think I should see as normal signal loss swapping from wide to narrow 500 filters (500hz in both IF's) when in the radio ? the new filter is the 8mc, don't have another low IF filter to try.

none of my other radios cause a loss of multiple S-units from ssb to cw. Anyone have an 830s with both 500cw filters can tell me what is expected S-meter sig loss (approximately) ?

I guess I'd expect 6-9 db worst case (an S-Unit or so)?

I really would like to put this thing back on CW and use it some - however, with this much RX attenuation it makes it somewhat useless.

just learning how to work on these things, trying to avoid non-productive rat-holes by asking the Obi-Wan Kenobi's in the crowd.

I am interested in "tweak the oscillator to the filter", as it may have to be done - how do I set that up, what is the best way to put a carrier on and "see" it in the scope/SA response?

I'd like learn how to optimize the alignment for my particular radio, not just settle for the stock procedures.

Thanks again for your help, Terry. I think you nailed it... after tuning the drive control with (!) scope probe attached :-) I got 160Vpp at the final board DRV pin at the maximum. The finals see only 120Vpp directly at the grid (again, after re-tuning drive for maximum...). Couldn't tune in with two probes attached (one at DRV pin, one at pin #5 of the finals).

I will change C1. Any special requirements (except 100pF, >= 500V)? Y5R ok?

Martin:

You are a little low with control grids seeing 120v P-P or 42.4 rms volts rf drive. However, at this level you should still see 100 watts output and not 70 to 80 watts output. For 70 to 80 watts output the RF drive at the 6146 finals would have to be approx 35 rms volts or 99v P-P. So the problem to me seems to reside inside the PA cage and not in the Driver stage. Driver stage appears a little low and could be improved upon, but I dont think it is cause of low RF output power.

I doubt C1 is the problem. The service manual just ahead of the Parts List provides all the detail you need to spec all the capacitors in the radio. In this case it is a Type 1 RF temp coefficient capacitor. It is a N330 with a green dot. You may have problem finding one. If you cant find a N330 then use a modern "COG" type or even a NPO "black dot"). If forced to use a Class 2 cap then make sure that the wvdc is at least 500 volts.

Here again are suggested items:

1. Try another known good 12BY7A tube
2. Measure 12BY7A anode and screen grid voltages in Tx mode (SG is most important)
3. Are you certain you have performed the Coil Pack alignment properly? I have description on my website on how to adjust the Drive coils so that the peak occurs very close to same place as it does in Rx (using Marker sig).
4. Did I understand that you swapped 6146 finals and are certain that the Finals are not soft?
5. Did I understand that you have normal 6146 final SG voltage? (very important)
6. C29 .01 dc block could be bad, but again never seen one.

7. Given age of the Plate block and RF bypass capacitor I would change both. I always change them on customer radios.
8. Make sure no axial motion on the Plate Load capacitor plates. The back bearing point is sealed with white paint. Make sure still in place and you can see no plate motion when you thrust drive shaft forwards and backwards.
9. MX-2P relay contacts are good.
10. With rig downpowered and HV supply discharged tug on both Plate Parasitic suppressor leads at solder lugs to make sure not loose in sublimated solder joints. Sometimes will pull out of perfect round hole in the solder.
11. Good visual inspection of the RF plate choke. Especially no discoloration in the center of the windings.
12. Final board mounting screws all torqued.

DRV is a little low which of course it follows that the output of C1 to control grids will be correspondingly low.

You report 160v P-P at DRV wire wrap post. 160P-P = 56.5 rms. This is a little low with exception of 10 meters. At 20 meters 14.2 mhz I would expect to see approx 65 rms rf volts

at DRV.

Most common causes for low RF drive to the 6146 final control grids on all bands are:
1. Weak 12BY7A driver tube
2. Low driver tube screen grid voltage
3. Poor coil pack alignment

This assumes you have normal TIF and normal VCO (LO) and normal RF drive from the TX Mixer (2 to 3 rms rf volts at TP-4)

Make sure to eliminate all the common problems before replacing disc ceramic capacitors. Disc ceramics seldom the problem but often changed out. Not sure why?

20 db is not correct. Filter data sheet states approx 6dB and that is close to what you should see.

With VBT full CW and Drive control peaked using Marker signal on 20 meters at 14.2 mhz should see S9 in CW wide and when flip to CW-N should see S8 ie 6dB. Same if you inject 8dB or -105dBm into the SO-239. Should see very close to loss of just one S unit (S1 to 0). Assume radio aligned per the Service Manual.

Same on 80 meters. You of course may have to touch the VFO to peak signals in both CW-W and CW-N modes.

This years 2015 Kenwood Legacy forum Power Point presentation is up on my web site and can be viewed at:

WB4HFN Home Page Drake Home P http://www.wb4hfn.com/KENWOOD/Hamvention_Forums.htm

I hope everyone had a good time this year and found the material interesting.

I counted 80 people that attended the forum this year, compared to about 35 last year.

Thanks,
Mark, WB0IQK

52097. Re: [Ts-830s] Term impedance for YK-88 filters?

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-05-19 14:40:16 UTC
From: wagstw46@...
Topic: 52086 Message: 52097

I forgot to mention that on my website www.k9tw.com http://www.k9tw.com under the Pictures button I have Spectrum Analyzer screen shot of a YK88S1 filter terminated with simple 620 ohm series source resistor at filter input and a 620 ohm shunt resistor at output and a screen shot with no resistive terminations. I also have shots somewhere using couple of 10 turn trimmer pots on each end to form L-pads at each end. Didnt make a big difference so for a go-no-go screening test on used filters I just use single resistor at filter input/output. Also have them for the 500 hz CW filters as well. When get time will find and post them.

Had one fellow yesterday ask about the response he sees on CW filter using noise generator and audio spectrum analyzer software on his lap top. Response curve wont be nice bell curve. The filter is not bad. It is normal to see the high end fall off sharply. You are not looking at the response due to the filter action. KW design changes the radios audio amplifier frequency response in CW mode to enhance 700 to 800 hz note copy. If you look at the Audio boards will see a diode switched RC low pass filter arrangement.

Terry K9TW

Bob:

I had a somewhat similar experience when I first got my (used) TS-530S. I bought it at a hamfest, and also purchased a narrow (250 hz) Kenwood filter from the same seller at that time. When I got the rig home, I installed the filter in the rig and proceeded to "fire it up". I used it for about a year, but was disappointed in the "narrow" CW filter operation; it seemed to produce a significantly attenuated signal, so much so that many of the weaker CW signals which were audible using the SSB filter were inaudible with the 250 hz filter (despite being tuned to the center frequency of the 250 hz filter). Then I replaced the 250 hz filter with (another newly purchased) 500 hz Kenwood filter, and performance was much improved (no significant received signal attenuation when switching to the narrow CW filter). I did not have any equipment to measure the performance of the 250 hz filter, although I doubt that it was the 20 db of additional attenuation that you seem to be experiencing.

I surmised that perhaps the 250 hz filter inherently produces more mid-band attenuation than the 500 hz filter, but maybe that's a bad assumption to make- maybe the 250 hz filter was, in fact, somewhat deficient in performance compared to what it should have been. It had been removed from a previous rig; maybe the de-soldering as part of the removal could have damaged the internals? In any event I'm still living with the 500 hz filter, and it's sufficient for my CW operation. I still have the 250 hz filter somewhere...

If you can, please let us know of any measurements that you perform on your filter.

52099. Kenwood TS-850S stuck in transmit mode when turned on

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-05-19 04:34:54 UTC
From: JF
Topic: 52099 Message: 52099

Hello all,
I'm a new member, and others suggested that perhaps someone here will have ideas for repairing this TS-850S problem.

This rig had been working fine for years, then sat unused for a few months, unconnected to DC power, antenna, mic or key. When powered up again it immediately went into continuous xmit mode (like tune mode or keyed CW) and could not be made to go back to receive. The front panel xmit power and carrier controls function, and there is continuous RF power output in all modes despite no keying. Checked all front panel controls (including SEND & TUNE) & plugged/unplugged all cables, but this made no difference, nor did a microprocessor reset. Frequency display & LEDs are normal, power supply is OK at 13.8 VDC.

A search turned up an owner's comment on another list about a similar or identical problem, saying that his BK Switch Unit pcb (BK SW, a very small board soldered onto the IF Unit) had transistor Q3 shorted, thus locking the SS line into SEND mode. I checked the 11 pins of my board with a meter:

pins 1 & 11 = ground
pins 2, 3, 5, 7 = 0 V
pin 4 = .012 V (SS line, low V puts radio into send mode?)
pin 8 = 5.14 V
pin 9 = 3.95 V
pin 10 = .021 V

I could not find an individual pcb connector for the SS line, but as it goes through the large CN3 ribbon connector I tried unplugging that, whereupon the radio returned to receive mode.

This may indicate a faulty SMD component on the BK SW board, but I'm not sure as I don't know the signal sources, levels & their effects on the other pins. Or, I suppose it could be something else forcing the BK SW board into SEND mode. As this has happened to other owners possibly there is a known design defect, or maybe some weak components got on the assembly line. I only have the short instruction manual and a PDF copy of the service manual, the latter being rather vague and hard to use for troubleshooting with its split blurry diagrams and connector designations that are not exactly the same as those printed on the boards.

I don't have tools for SMD solder work, and I'm wondering if sending the whole heavy radio off for repair might cost more than it's worth. I'd rather locate a new/used BK SW board to substitute, or a whole IF Unit. Or, is it possible to send just the IF Unit to someone who works on Kenwoods? Any recommendations for repair shops?

Suggestions will be much appreciated.

52100. VFO-230 Problems

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-05-19 23:01:53 UTC
From: Joe Reed
Topic: 52100 Message: 52100

Dayton was kind to me this year and I came home with a VFO-230. I knew it was rough looking and would need a repaint. And the seller didn't know if it worked. Hamfest speak for not likely. But it lit up when I got it home.

Issue #1: After it warms up the tuning becomes erratic. A search of the message archives strongly suggests the electrolytic caps need to be replaced. Since I'm probably not the first person to see this I wonder if anyone has complied a parts list with Mouser or other vendor part numbers.

Issue #2: The previous owner didn't cherish this unit. It was run hard and put away wet. At the Kenwood forum Mark, Jan, and Jeff gave me excellent pointers to obtain matching paint. But the front panel is also a bit rough. I know they are made of Unobtainium, but does anyone have an extra they are willing to part with? I'm not looking to restore and sell it. Ultimately it will get sold, but not until I cast off the mortal coil. And hopefully that's more than a few years away.

Thanks in advance,
Joe N9JR

CraigWhen I need to check a questionable mic I use a digital meter. I check across the mic cartridge while I talk into it to see if it is at least giving a voltage. This may not be an actual voice output, it does say the mic is giving a voltage.

THanks Lou. Sorry been delayed. I am a firefighter used to working 24 hours off 48. I have been put on light duty after shoulder surgery. This Mon- Fri 8 hour days kill me LOL. I have found that the mic is doing it's thing. I am going to have to check the tuning on the radio had a couple of contacts last night that knew I was there but they never could hear me well enough to make me out. Then again as old as the mic is and as rough as it looked when it got to me it still could be a mic issue. I wish I could remember where I saw the pictorial on tuning the 820s . I will search some more when I get back from games today with the less fortunate here at Miracle League of Whitfield County.

Just wonder if you have a key plugged in ? if you pull a key plug out the jack usually has a shorting contact that closes and keeps the keying line on. In one of the SSB modes this may prioduce a continuous side tone but no RF output. My radio is Ham Radio...CW is Real Radio

Joe

Try leaving it connected to power for snout 24 hours. This should fix the erratic tuning issue. I leave mine connected to power permanently, never had problems.

Your heart is in the right place, but a VFO-230 uses an optical encoder and not an air variable.

On the analog LC type VFOs a drop of D100L full strength Deoxit may be more effective than using multiple sprays of D5. A small bottle will last a very long time and also very effective on high resistance relay contacts.

Also not all of the analog VFOs have a side access plate. On the 530/830 models there is an aluminized taped over access hole, but better to pull the VFO and remove the shield can and you need to clean both the front and rear rotor shaft contact wipers.

Tim,

Tuning of the "VFO-230" is accomplished by an "encoder" not a variable capacitor. The VFO-230 is a "digital VFO".

The remote VFO you are referring to is the VFO-240 which contains the same "analog" VFO that is tuned by adjusting a variable capacitor. The VFO-240 has the same analog VFO that's contained inside the TS-830.

hi terry,
did the noise generator thing, as well. but that is as you say not just the filter artifacts, but the whole chain from the SO-239 thru to the sound card.

yepper, I saw the pics at ur website. As I recall that was right after you bought your new toy, the 815. heck of a bang for the buck. I need to play with mine more anyways !

I'll do same for my filter here and we can compare notes.

for all I know its low IF cw filter, but I don't have a spare for that. If it turns out that I don't need the 8mc CW filter, I'll just sell it as it wont be hard to get rid of it I don't imagine. not much else to go wrong in there unless its switching diodes etc.

personally I like to see a 600 hz note for cw as 800 is too high for me my ears... I can pick out a lower tone in the noise better.

The remote VFO-230 has an "optical encoder" and not the air variable like the ones in the other remote VFO series...(520....etc)..thus no "wiper" to be cleaned

Bob:

I added some screen shots both Spectrogram and DSA815 since I bought it. For the money it is an evaluable tool. I just hope it will be reliable over the long haul (at my age a relative term!).

Yes with the VBT and IF shift and no optional filters you can pretty much get single signal CW copy today during majority of the time. I suppose during weekend CW contest might be nice to have the 500 hz CW-N in addition, but I suspect CW bands are not as crowded as they were when the 830 hit the market. A full filtered TS830 was clearly among the contesters favorite in that era.

The audio response of the AF amp will copy 600hz note just fine.

Be glad to share filter sweeps with you. I also do them in circuit. Also look at and adjust the BPFs on the TS520 series and the PLL BPF filters on the 830. More commonly find the 520 Tx and Rx BPF coils messed with.

Early on when sweeping a filter I used the Delta Marker function and manually determined the 3dB or 6 dB bandswidth. I have since learned how to use Marker Fctn - N dB BW and set the function to whatever amplitude I am interested in most typically measuring the 3dB or 6dB bandwidth. Much quicker and easier. Still learning how to use this tool. Rigol has some good online tutorials and there are some good You Tube videos.

Much easier than setting up old Wavetek Sweep gen, diode detector, RF sig gen for the KW markers, O-scope in X-Y mode, and the associated cabling. Did it that way for a long time. Before that straight RF sig gen, RF voltmeter, graph paper, and pencil! Not too bad to see the as found, but not very good for adjusting.

Terry K9TW

Hello.
This is my first post, so I stand before the group.
My name is Rafael, I have 63 years old and my call is EA5TV, I live in Almazora (Spain), a small town east along the Mediterranean sea, 65 km north of Valencia.
My start in radio were in 1979, when my friend Dom, EA5TX unfortunately SK, taught me this wonderful world, so I took the test and got the call EA5BFX.
Due to personal reasons I've been 12 years inactive in radio, but since 2010, when I got my current callsign, I returned to operate my beloved TS820S, but so long without work has caused minor problems that already have been solved. It has made me rejuvenate 25 years.
Still I have a fault in the digital display. Occasionally disappears a number and other changes to "9", but not always. It stays there for a while and then returns to work well.
I've seen that it can be a problem welds in the DG-1 system and I have reviewed all the joints between the two sides of the plate X54-1160-00 unit.
I changed the components of the 5V-AVR I checked the voltage, and has 14.5 V but I do not know if this value is correct. I have also seen this happen if X43-1090-02 rectifier unit is in poor condition, but apparently okay.
I would be very happy to be able to operate this magnificent radio to 100x100
Best regards. Rafael. EA5TV

Rafael,
Welcome to the group.
Several things we need to know. Does the problem of changing to "9" happen on all bands? Does it happen when at the band edges? When the display shows "9", does the receiver seem to work ok? You should obtain a service manual. You can get one for no charge from:n6wk.com or w5rkl.com. The service manual has a troubleshooting section about your problems Before going to far, obtain some contact cleaner and clean all the pin connectors in the DG-1 unit. You will have to remove it from the radio first. Then put it back in, and retest. This may, or may not solve your problem.
Your translation program seems to be pretty good.

Hi Joe.
Thank you very much for your reply.
The "9" is displayed on any band, but the tranceiver continues to run smoothly.
I've already downloaded the service manual.
I'll find a good contact cleaner and do as you say.
Best regards.

I had pretty much the same symptoms with my radio I had bought after being out of the hobby for about 28 years. I found that the problem was in the CAR unit containing CAR 1 and CAR 2 boards. I removed both boards repeatedly and cleaned the post connections between the boards and the problem would be gone for a day or maybe an hour or so after I cleaned the connection post electrically tying the boards together and the display worked perfect for the period.
I cleaned and replaced them over and over and then one day I said to myself this will be the last time I have to do this. I took emery cloth I bought at the parts store and a old knife I keep around and I cleaned each and every post as I looked at them thru a magnifying lamp and when I knew I had them all cleaned as if they were new. I replaced the boards and to this day have had no more trouble. I hope I explained myself as I am not too good at this but I fixed my display once and for all. Good luck.

On my VFO-230 it became erratic as well. Going thru the service manual I found on the encoder board that VR-1 & VR-2 hadbecome corroded and a little Detox and working the VR's and resetting them to the proper voltage it became very stable again.God Bless all, Bill WD8OSJ

52116. Cabinet paint source?

I'm in the market for some cabinet paint. I bought the one that's on eBay but didn't have good results. Looks like I'll be sanding back down tomorrow.

I've used this one in the past and would like to find a can of it http://imgur.com/iDVirQn

Anyone know where I might be able to buy a can?

Thanks 73,

Tyler

Topic: 52117 Message: 52117

I installed the filter for CW Fox Tango YF-88H250 and really works very well. It's a real knife, but I've noticed that when I operate in CW transmission frequency is different from reception. For example, if I get a station in 14.020.0 kHz and answer his call, the transmission frequency is 14.020.9 kHz. Is this normal or I have to make some adjustment to have put the filter ?.
I have another question. Really good product that I can buy to clean the contacts?
Thank you.

52118. Kenwood PanAdapter, PS, cable, manuals FS

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-05-22 15:35:14 UTC
From: Ken Simpson, W8EK
Topic: 52118 Message: 52118

Kenwood Items For Sale:

BS-8 "Pan Adapter" Band Scope, heavy duty power supply,
Cables, manuals, and more

Kenwood BS-8 "Pan Adapter" For Kenwood SM-220:

The Kenwood BS-8 is a panoramic display option (sometimes called
a "Band Scope") for the SM-220 Station Monitor when used with any
rig with the 8.83 MHz IF frequency, which includes the Kenwood TS-820,
TS-830, TS-850, TS-180, TS-530, TS-930, TS-940, TS-950 and maybe others.
The BS-8 installs inside the SM-220 without soldering or special tools.
Minor wiring is required for the TS-820S and some other units. The
SM-220 then can display a ± 20 kHz or ± 100 kHz portion of the spectrum.
The pan display employs a logarithmic compression system, so weak
and strong signals can be monitored simultaneously.

This particular unit works fine and looks fine also, as if looks matters,
since it is installed inside the SM-220. It includes all cables and
hardware required for the installation, along with paper work for
only $150 plus shipping from Florida.

Kenwood PS-30 power supply

This 20 amp 13 V DC supply was originally made to go with the
Kenwood TS-120/130 series of transceivers, but it also matches
the TS-430/440, and is actually a much more rugged power supply
than the PS-430 often used with the TS-430 or TS-440. It features
large heat sinks and automatic overload reset. Ripple voltage is
less than 20 mW at 13.8VDC 20 A.

The PS-30 has a heavy duty power cord with the standard 6 pin
molex connector as used by many Kenwood, Icom and some Yaesu rigs.
It also has terminals on the back for lower current output, such
as for a 2 meter or dual band rig.

This one works fine and looks good as well. It includes paper
work for $125.

Linear Amp Switching Cable for Kenwood Rigs:

This cable goes from a Kenwood transceiver to a linear
amplifier to switch the amp from transmit to receive.

One end has a DIN connector, as is used with most Kenwood
rigs. The other end has an RCA phono plug, as used by most
linear amplifiers.

Before using this cable, please check the switching
capabilities of your transceiver, and the requirements
of your amplifier.

This cable is for switching the relay. $15

Original Manuals for Kenwood equipment:

All manuals are in very nice condition, for Kenwood equipment.
All are Operating manuals unless otherwise specified.
All are original manuals only.

SPECIAL:
Buy two, three, or four of my books/manuals, and take 10% off.
Buy five or more and take 20% off.

TH-21 HT for 2 m, $8
TH-215/315/415 HT for 2 m, 220 MHz, or 440 MHz, $10
TH-225, 2 m HT, $12
TH-235, 2 m HT, $15
TH-241/441/541 mobile FM transceivers
...For 2 m, 440 MHz, & 1200 MHz, $12
TM-221/421 2 m or 440 MHz mobile, $12
TM-261/461 2m or 440 MHz mobile, $12
TM-2570/2550/2530 2 m mobile, $15
TR-2400, 2 m HT, $12
Service manual for TR-2600, 2 m HT, $12
TR-9000, 2 m multimode, $12
TS-120 S/V, HF xcvr, $20
TW-4000 dual band mobile, $15
Service manual for TW-4000 dual bander $20
TW-4100 dual band mobile, $15

BC-5 DC to DC quick charger $2
LF-30A Low Pass Filter $5
MC-30 & MC-35 hand microphones $4
MS-1 mobile stand $3
PB-1, PB-2, PB-3, & PB-4 battery packs $3
PB-24 battery pack for TR-2400 $2
PB-25 H battery pack for TR-2500 $2
PS-6 power supply $5
PS-30 power supply $4
SMC-24 speaker mic $3
SMC-25 speaker mic $3
SP-430 speaker $2
SP-820 Speaker $2

These are original Kenwood manuals only.

I also have many other accessories available such as many
different types of microphones, HTs, HF, VHF and UHF rigs, HF
and VHF/UHF antennas, etc.
Just too many to list here. Please e-mail your requests.

Prices do not include shipping from Florida.

Thanks.

Rafael,

Yes, it's normal for the 820's CW frequency to shift 800hz in CW transmit. You can see this by studying the TS-820's service manuals' Circuit Description section that covers the 820s PLL Unit. You can also see the change in the PLL Unit's block diagram on page 8, Fig 3 TS-820 Frequency Diagram. Also study page 10 Fig 6 block diagrams of the PLL system and Fig 7 PLL assy.

52120. 830S AGC problem?

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-05-22 15:18:32 UTC
From: DavidN
Topic: 52120 Message: 52120

Hi guys. I recently bought an 830S off Ebay and it has a couple of problems. Neither problem stops my operating of the rig but they're just irritating. In this posting I'll just concentrate on a possible AGC fault, rather than the RIT one.

Firstly, I've checked the volts. The -6v, 9v and 3.6v lines are spot on. The rig is a Gold version.

What I'm finding is that if there's a weak signal at S0 and it starts to come up in QSB the S-meter stays at S0 until suddenly the S-meter jumps to S5 and the signal is much louder suddenly. This is with the RF Gain fully clockwise. This initially sounds like an S-meter circuitry fault but read on.

I've found that if a signal is *steady* at S0 and I *decrease* the RF Gain control the signal comes up in sensitivity along with the noise. The signal continues to rise until at S-meter reading S3 it plateaus out til about S6 and then starts to decrease as normal. As we all know, decreasing the RF Gain control from fully clockwise should decrease the signal, not bring it up! i.e. it acts as an attenuator.

So, if I set the RF Gain control to number 7, I'm finding that the sensitivity is about two S-points better than when it's set to 10.

Firstly, I've disconnected and reconnected all the plugs on the IF and RF boards. I've also unscrewed slightly and rescrewed all the screws on those two boards too. I've also re-aligned the IF sections according to the Service Manual, they weren't that far off at all. The S-meter has been set to zero when connected to a dummy load. I've checked R149 2.2M and it reads spot on. The OFF, FAST AND SLOW positions of the AGC control work fine. This is all with the HEATER switch set to off. However, I've been unable to measure the AGC line because of its very high imperdance - my multimeter must have an impedance of 2Mohms at best.

I've come to the conclusion, and perhaps you can back me up on this, that in a correctly working rig, when you lower the RF Gain control you're lowering the volts on the AGC line. So if the signal actually comes up when you lower the RF Gain control there must actually initially be *too many* volts on the AGC line. And by bringing those high volts down you're bringing the volts down to a level where the AGC line has been designed to run with correct biasing on the RF/IF devices.

If that reasoning is correct, then something is putting too many volts on the AGC line. With this in mind I've tried to measure the volts around Q9 and Q10 on the IF board but they're so tight to the IF board it's impossible. And I'm unwilling to pull out the IF board as I've found it can cause more problems than it solves.

Two other points are that on 14.175 with the Calibrator on I'm only getting S4 on the S-meter. Also, I've never yet seen a HF signal go above S7 on the meter when I can tell the signal is a good 9.

Any thoughts please? :)

David G4TUP.

It looks like a custom-mix from an AllPro dealer. There's a number on it so it may be reproducible or at least matched, especially if there's any left in the can. The UPC code is probably for the base. Hopefully there's an AllPro store near you:

Thanks, Bob. I called several dealers from that website and none of them sell AllPro. Odd!

However, I found a local paint store that can mix and they send off the paint to be put in cans. $10 for the can + cost of paint. Not bad for a single can! I may do a bulk order and sell them at cost since I have to buy the paint anyhow. It's been difficult to find a single can of paint.

David:

Some thoughts:

1. Yes the AGC bus (rail) is by design an high impedance power supply. As you note it is fed from the 3.6vdc RF -1 reference voltage thru a 2.2 meg resistor. You will need at minimum a 11 meg VTVM or a 10 meg DMM to measure it. Some DMMs are as low as 900k input Z on low ranges and many are 2 to 3 meg and will shut the receiver down. A true 11 or 10 meg meter on the 5 vdc range will pull the bus down from 3.6vdc to approx 3.0vdc and drive the S meter up to approx S4.

2. The AGC bus is not technically "bias" although even some of the KW literature refers to it as bias. I think that is a translation problem. It is a servo or control voltage that is supplied to Gate 2 of the gain controlled devices. All of these dual gate mosfets do have dc bias voltage applied to Gate 1 to set the Q point of the amplifiers.

3. You mention aligning the IFTs but I dont see any reference to the front end. If you have not done the Coil Pack alignment need to do the Ant and Mixer coils per the band and frequency chart as a first step.

4. Next you need to calibrate the S-meter. It is a three step procedure. A. Zero set on dummy load for no signal B. Set the AGC threshold by inputting a 8db or -105dBm or 1.26uv signal into the SO-239 and adjusting L9 on IF board for a S1 S-meter indication C. Injecting 40 dB or -73dBm or 50uv for an S9 indication. All done on 20 meters at 14.175

5. Q9 is a buffer amp that takes small sample of RF signal from last IF stage and supplies it to the AGC detector diodes. These diodes are back biased by the -6vdc supply. Q10 is the AGC amp and it is essentially and electronic load with the collector hanging on to the high impedance AGC rail. When Q10 gets biased on by the AGC detector diodes it pulls the AGC bus rail down from its 3.6vdc reference level and drives the S-meter upscale. When the rail voltage goes down this lowered dc control voltage to the Gate 2 of the gain controlled devices reduces their gain. Of course there are some RC time constants involved here and they are different in Fast and Slow and different for the RF amp and IF amps. The change in control voltage to the RF amp is staggered or delayed in time so that the servo loop doesnt become unstable. The values were also selected to prevent AGC hang up on noise pulses.

Very seldom do I find a problem with any of the AGC time constant RC components. There are people who dont like them as speced and feel that the 830 audio is too raspy on strong signals. KW messed with RC time constants and bypassing the AGC line on each of the production runs. Depending on what serial number rig you have and if it has the original IF and RF boards you may have different RC time constant components from what appears on the schematic. I would not worry about changing any of the associated electrolytic capacitors until you have done complete alignment and proved that with the Service manual signal levels the AGC threshold is per design and the S-meter can be caled.

6. Yes KW did us no favors with component density and active devices with very short leads making it very difficult to take DC and signal voltages from the component side of the

board.

I forgot to mention for an S9 marker signal you will see something close to 2.2vdc on the AGC rail with a 11 meg VTVM.

If serious about servicing these radios on a large scale best meter I have found for AGC and ALC bus/rail work is the old HP-410C which has better than 100 meg ohm input impedance. Has no effect on the bus voltage.

As long as you understand what would be normal S-meter levels with a 11 meg or 10 meg meter on the bus then fine to use those meters for troubleshooting. There are some 22 meg VTVMs out there but dont see them often. Very easy to take resistors from junk box and see the effect on the bus by looking at the S-meter when you touch the resistor from chassis ground to AGC bus. Good way to figure out what input Z your meter really is. Assumes calibrated S meter circuit

Thanks so much Terry for going to the time and trouble of explaining things

in so much detail - going through the circuitry and confirming what I felt

was the way the rig was operating and designed, and mentioning some points

I was blury about too :)

So, re. your point 5 about Q9 and Q10. If there was a faulty component around Q9 it could be putting out more voltage than it should? R66 330k for example. If this had gone high then there wouldn't be enough negative feedback?

I guess the first thing is to align 20m and then I can calibrate the S-meter properly. I do have all the necessary equipment. I did align the 160m RF section, as in the Service Manual (basically peak the 160m ANT and RF coils on 1.9Mhz).

But as you say, best to check all the other bands too, then we know the rig is up to spec on all bands RF and IF-wise.

After using a not so highly specd multimeter I won in a local contest group :) I've ordered a 10Mohm input impedance one off Ebay: http://www.ebay.co.uk/itm/321134863493

So then your AGC line voltage comments can be compared....

Regards and again thanks, David G4TUP.

Rafa,

The CW side tone is not used in receive CW tuning nor does it have any control over the transmitter's frequency in CW transmit.

The CW side tone is NOT transmitted in CW mode as some hams have been misled to believe.

The CW side tone has 2 functions only:

1. Supply a CW keyed tone in CW transmit that is fed to the VOX Unit to activate the relays (switch the 820 from receive to transmit).

2. Provide a keyed tone so the operator can hear his/her CW dits and dahs during CW transmit.

The length of time the transmitter remains in transmit (VOX Unit activates the relays) is controlled by the VOX DELAY control.

Q9 is a buffer amp. It is an ac coupled emitter follower. There is no voltage gain. Q9 isolates the AGC detector/AGC amp from loading Q8 the last IF stage. There is no rf signal feedback associated with Q9? R66 sets the base bias of Q9. The emitter resistor R67 is called the emitter feedback bias resistor. This config results in very high input Z and low output Z thus the Buffer action.

Until you do a proper and compete RF and IF alignment and calibration of the S meter circuit it is too soon to be looking at resistors and capacitors as the problem.

52133. Hybrid Net Update (May 24, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-05-24 22:54:22 UTC
From: Mark Gilger
Topic: 52133 Message: 52133

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by Jimmy, WB2KNR.
There were 17 stations checking in under fair band conditions.

We had the following number of radios checking in.

5 running TS-520(x)
0 running TS-530(x)
2 running TS-820(x)
1 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

Jimmy was running a TS-520.

The Sunday net was run by me, WB0IQK. There were
12 stations checking in under poor band
conditions. We had the following number of radios checking in.

1running TS-520(x)
1 unning TS-530(x)
0 running TS-820(x)
1 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-940S + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome

as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit

I recently replaced at the electrolytic caps on this radio and I am not getting any receive, no white noise at all. The only thing I get is a low freq hum when I use my headphones I can hear it.
This radio had been idle for the last 15yrs or so.
Where can I start to find the problem.

Thanks

Had the same problem with my TS-830S after replacing the caps. The wire connecting the IF-board with the -6V supply was broken, only low hum and no bright noise to hear in the phones.

Check the supply voltages at all boards!

Martin

To close this case: it works now, the TS-830 delivers 100W with 225mA plate current (and >120W during tuning with >225mA). A new set of finals and a new driver tube did the trick.

However: RF drive is still less than that in the TS-520. The swapped-out tubes work flawlessly in the TS-520, delivering >100W. I found the file "checking finals" in the file section. Doing this, I checked the four sets of 6146B I have. The two sets I got with the TS-830s (one installed, one spare) gave 170mA with this test (old RCA) and 155mA (no name, made in china) at maximum bias. The S2001A and the new set (NOS GC) gave >250mA each. The NOS set delivers 100W RF @14.175 and 225mA plate current in the TS-830, the old RCA set delivers about the same in the TS-520. I will keep the S2001A-set as spare. Both give about 80W@28.5MHz, this is expected.

One thought: the TS-830 has negative feedback. Could this explain the different behaviour with older (weaker) finals? I'll try to locate a spectrum analyser and check the quality of the signals....

Thank you very much for your input, this group is a great place to learn!

73,

Martin DB2MJ

Jesse,
FYI, you can also use a VFO 120 with the 530S. If you're just looking for the functionality (eg. working split) it gives you another option but if you're looking for the visual and functional match you'll want the 240 or the 230. I'm using a VFO-120 with my 830s. Works fine.

Topic: 52086 Message: 52146

well, this is my luck. I put the 500hz 8.8 mc filter on the spectrum analyzer and it looks like an open circuit. another typical Ebay "excellent condition" deal. To be fair, most people selling the filter probably don't have any means of knowing if it was good I guess.

there is no discernible response peak anywhere near 8.8 mhz... in fact, none really at all - almost as if the TG is turned off... as a sanity check I popped in a little IF transformer/capacitor that I was already familiar with which had a known response... all ok... checked the circuit board to ensure I was using the right pins etc...

so I ruled out a grey matter problem.

I'm surprised at this failure mode as I would have thought them to be near bulletproof. So, until i can appropriate another 500hz CW filter, I'm stuck.

tnx for all the input guys. When I get another filter that looks good, I'll refresh this topic.

In my experience this is a very unusual failure.

I usually start with TG level at 0dBm (224mv), Span at 10khz, RBW at 300 hz, and VBW at 100hz.

You can also place RF millivolt or O-scope across the output and drive it with standard RF sig gen and step the sig gen and watch the RF output voltage peak.

I've listened for both the Saturday and Sunday nets each of the past 4 weekends, unable to pull anyone out of the noise for the nets. I hear another Weekday morning net on 14.304 and talk back, net control is in north Missouri. I hear the ten-ten net, the Saturday morning nets, the Weekday evening nets, some net controls on 14.300, yet cannot hear either Kenwood hybrid net. So it seems the propagation bounce is not bouncing my way or their beam isn't pointed to the deep south.
I've logged plenty on 15, 20, and 40m via SSTV, PSK, JT65, FreeDV, so I know I get out and receive fine. I will keep listening and if/when I hear it I will check in.

If you are just flipping from CW -Wide to CW- Narrow while copying an off air signal or the Marker signal then very likely an S9 indication could fall off to S1. Have to get a hold of the VFO knob and vary it and should be able to bring the S meter indication back up on the Narrow Filter.

If you cant bring it back up by adjusting the VFO then there is a problem. Insertion loss of the 250 hz filter should be approx 8 dB. 1 S-unit is approx 6dB.

I’ve looked as well. You can get what you want from Digikey but it’s $30. I think a couple of China ebay vendors have them but I seem to recall that option being over $20. ebay always has ones priced very dear as well – when they come up which is not often. If you find a source, I’m on the hunt for another couple myself!

Good luck.

52158. TS830S Cathode Resistors Keep Blowing

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-05-28 14:41:27 UTC
From: danbbower@...
Topic: 52158 Message: 52158

Hi All

I am slowly trying to get my 830S back to full health and am struggling with the finals section.

I have replaced C7, C8 and L1 as well as the screen and cathode resistors using parts supplied by Ken K4EAA. All worked fine and managed to make a contact or two.

However, having powered everything down overnight then replaced the HV filtering caps and the screen caps, I switched it all back on and during the tune up process (following K4EAA's method to the letter) the cathode resistors blew(and I mean properly - with a bang and everything).

I have since replaced them twice as now they are blowing merely when I have the plate dial set roughly to band and without send being switched.

The rig will sit there quite happily for hours with the heaters turned off but the moment I turn them on - bang.

I have tried a new set of finals (NOS) but with the same result.

Any suggestions as to where to start with a diagnosis?

Thanks all for your help.

Check the PA tube voltages.
Sounds like the grid voltage is way off, so the tubes are conducting as
soon as the heaters are turned on.
You might do the cathode protection mod, using the three 1n4007 diodes
in series to the cathode and ground (band side to gnd)

Measuring the 6146 grid voltage, pin 5 on either 6146 tube socket, in standby should be approximately -105VDC or so, dropping to approximately -67VDC in transmit.

The 6146 pin 5 tube socket voltage can be measured by setting the SG switch to OFF, with or without the heater switch set to ON. If you use this approach the cathode resistors should NOT blow as there will be no cathode to screen/plate current. The cathode voltage, pin 1 on the 6146 tube socket, with this arrangement (SG switch set to OFF and with or without Heater switch set to ON), should be very close to 0VDC. With no current flowing in the final tubes the cathode voltage should be 0VDC.

Danny,

Setting the final amplifier's 60ma idling current is discussed on page 17 of the TS-830 operator's manual. If you do not have the TS-830 operator's manual, go to my website

www.w5rkl.com

and click on Manuals and Documents. When the page comes up, scroll down to the TS-830 operator's manual, #16 on the listing.

Thanks guys for your help so far.
So, I have measured pin 5 and I get very confusing results. In receive I get c. 1.6v and in send c. 0.67v. To check the voltmeter I tested the top of L2 and got just over 1kv so I'm pretty sure it's working OK.
Am I missing something obvious.
Note also as a test I briefly flicked SG to on and the finals started glowing like a dying star. Switched it off again this time before doing any damage to the cathode resistors.
Also, don't know if it's significant but I cannot bias the finals either. The needle sticks on just a few mA.

It appears it's possible the -C bias supply on the Rectifier Unit has failed. Most likely C5 and/or C6 are shorted to ground causing D5 to fail resulting in zero -C bias voltage. You can verify this by measuring the voltage on the Rectifier Unit's "-C" terminal, you should see approximately -110VDC or so. If you do not see any voltage on the -C terminal then replaced C5, C6 and D5. D5 can be a 1N4007. C5 and C6 are 33ufd 160VDC axial lead capacitors. Make sure you pay attention to the capacitor markings and the diode's "banded end" so you install them correctly.

You have some _serious problems with the tube's voltages_.
You did something wrong when you re-capped the HV supplies, I guess.
1,000V on the plate is WAY too high; Pin 5 is also way too high, should
be -100v on RX, about -50v on TX.

Hello group,

In part of our radio club's hams helping ham's initiative, I visited one of our part time residence member's since he was having radio/antenna issues after moving back to the area for the summer.

The antenna SWR checked out good using his tuner through my MFJ Analyzer. The issue was while he was tuning up during one key down he adjusted the SWR fine, un key wait a few seconds key again there was a different SWR forward-reflected power reading.

Without much equipment on site or the time to rip the rig apart, I don't have more info to provide at the moment, yet it gave me flashbacks of my TS-520S a few years back that dropped power during a conversation, and the other party said it sounded like I had "RF" on my signal. End result was the power caps had seen better days.
Gus, is the second owner of the rig having had it for most of the time since it was new, with never a repair.

I have downloaded the service manual, and it looks easier to replace than on the TS-520S that I have. Unless someone has some other thoughts of what I should look at to help out our fellow ham, my action plan will be to let him order the parts for replacing the power caps, maybe scan over the finals cage and resistors below while I have it open, don't want to mess anything else up since it other wise was working fine prior to it's drive from FL to NC.

Thanks for any comments

James WS4JH

I read Danny's voltage measurement response again.

It appears the Rectifier Unit's -C supply is working. This is evident by setting the SG switch to OFFwhich keeps the 6146s from glowing like a dying star.

Setting the SG switch to OFF applies a "negative -C" bias supply voltage to the 6146 screens (pin 3) which blocks the flow of electrons from the 6146 cathode to the plate resulting in no electron flow in the 6146s so the tubes will not glow like a dying star.

However, setting the SG switch to ON applies normal "positive" screen voltage to the 5145 screens (pin 3). With less than a volt of grid bias voltage on pin 5 of the 6146s will cause the tubes to conduct to saturation levels in "receive" AND "transmit" which is why Danny sees the 6146s glowing like a "dying star" in both "receive" AND "transmit".

If cleaning the bias pot does not fix this problem then I suspect Danny's problem is caused by a failed relay on the AF Unit.

The problem is not caused by high 6146 plate voltage. It's normal for the plate voltage to be high when the 6146s are not conducting. When current flows in the 6146s, a voltage drop occurs in the 6146 plate circuit causing a "reduction/decrease" in 6146 plate voltage. As current flow in the 6146s increases, the higher the voltage drop will occur in the plate circuit resulting in a "decrease/reduction" in plate voltage. This is normal for vacuum tube operation.

I agree it's a good idea to install the 6146 cathode diode protection component but the lack of the cathode diode protection component is not the source of Danny's problem.

I have been following this thread for some time. I have years of experience with wire-wrapping, power wire-wraps work great...hand-wrapping...uuhh..not so much.

Back in the day, when wire-wrap first came to TV chassis/PC Boards, bad wire-wraps were the cause of many intermittent TV problems. My one boss (I was working for a TV service guy while in the military) used to go thru a TV brought in for service (remember when they did that!?) and put a touch of solder on each wire-wrap joint...99% of the time the problem would vanish.

So when I got back out into the engineering world, I was skeptical about wire-wrap until I started using the tools from Gardner-Denver. They have enough power to actually work-harden the wire as it past each corner of the pin making a gas-tight seal. (That is why the pins are square with sharp corners and the wire is round!)

My recommendation...and it is worth every cent you paid for it...is to go ahead and attempt the hand-wrap tools. But don't be surprised if you end up going back a few weeks later and soldering the joints.

In the late 70s during university I worked as a "Werkstudent" at the Siemens factory in Karlsruhe. Part of my job was to change wirewrap-backplanes for automation systems from rev. X to rev. X+1. Usually, this meant to unwrap several wires and rewrap them differently. I had a mechanical unwrap-tool and two different wrapping tools: one hand driven "pistol" and a electrical auto-wrap tool.

I never managed to wrap a wire with the "hand-pistol" to the satisfation of the head lab mechanic. He would check each of my wrappings and cut the wire if they weren't good enough... needless to say, I gained lots of experience. One important lesson was: never follow one path from the beginning of the backplane till the end. if you dov this, you wrap pin "x" at slot 1 and go to pin "x" on slot 2. To connect slot 2 with slot 3, you wrap the wire on top of pin "x", slot 2 and go to pin "x", slot 3 and so on. The problem is that you can unwrap the top wrap without disturbing the lower one, but not the lower one without disturbing the upper one. One error in the beginning of the path and you will wrap several posts multiple times.... Go from slot 1 to slot 2, from slot 3 to slot 4 etc. and then wrap the connections from slot 2 to slot 3. This way, you have the connections from "level 1" to "level 1" and "level 2" to "level 2". Much easier to correct errors.

Those were the days... I built an Apple II-clone completely from parts and didn't get it to work. The head mechanic took the mainboard, went to the production line and let it run over the wave solder machine... that did the trick. Used that thing for several years until I could afford to buy an Atari ST.

Forget about wire wrap with hand tools, you'll be unhappy with the results....

Martin DB2MJ

I worked for DEC in the late 60’s and early 70’s. All of the computers used wire wrap backplanes. Over 90% of the computers did not work out of the box after shipping. The Gardner-Denver machines used to wire the back plane would pull the insulated wires tight around the sharp pins. The shaking during transit would cause shorts. This made troubleshooting a challenge on the old transistorized machines. With the drawings, an oscilloscope a box of transistors and the wire wrap tool we would repair the computers. DEC trained us for 6 months prior to sending us to the field. I never had to solder any pins. We did have problems with some longer runs of single strand wire. The fix was to run twisted pair with one lead tied to ground on each end. The clock speed of the DEC-10 was 1 meg.

BTW, I was a Navy ET and worked part time repairing TV’s when ashore. $5 for black and white, $10 for color, $5 for turntable fixed rate. Good experience, bad pay.

73,

Gary

Antonio,
The "CWT" or continuous wave (Morse code) tone, is used to set the frequency of the "side tone" of the CW audio signal to YOUR preference. It does NOT affect your transmitted signal. Key rig in CW and listen for the tone from the speaker/headphones...adjust to a frequency that YOU like. Some like it a bit lower as they may have lost higher frequency hearing.

Step #7 service manual: Adjust VFO. The scale of the VFO is off by several kHz. Following the service manual, I tried to adjust the scale at the "50" and "450" position. Problem is: the two adjustments (L3 and TC1) are closely coupled. If I set L3 to the lower point, TC1 is completely off. Adjusting TC1 will throw L3 off etc. pp.

Any special tricks how to get these two to behave? All I managed trying for the better part of 2h is to make it worse...

Martin DB2MJ

52184. TS-520 -6vdc is -3vdc?

Good morning everyone.

Well here is what I have. I picked up this radio after sitting for at least 15yrs from an SK estate. I have recapped all electrolitic caps except the cap on the RF board. I can't figure out how to change it out. My problem is that I don't have receive at all, not even meter movement. Someone suggested I check the -6vdc on the IF board, well I could not find a place to measure it so I went back to the source on the RF board and measured the -6vdc past Q11. I am getting -3.25vdc at this point. Also the 2 big metal transistors Q3 and Q4 are very very hot.

I could really use some help on this radio. I have invited the sons of the SK to our field day event and would LOVE to have TS-520 up and running and have them make a few contacts on the radio there Dad used.

Thanks
Carlos

The hand wirewrap/unwrap tools you see on eBay and Amazon are NOT what you need for working on a TS-520. They are only for use with 28-30 gauge wire (teeny tiny wires). I use one these tools for breadboarding of some Arduino projects and for attaching wires to LED's and trust me, the wires in the 520 will not fit these devices and the flimsy 30gauge wires will probably not handle the current.
As someone else mentioned (K9TW?) the best way to re-attach the wire wrap wires to the posts is to strip the wire back to bare, give a little sanding to the post, give it a wrap or two around the post by hand, and then tack solder it.

Hi All,

I'm beginning to think I may have an antenna problem. I see S6-S7 noise on USB over all of the 20M band. I'm running a TS830S and G5RV at about 20 feet above ground. At least some of the noise sounds like a frying noise.

Doesn't that level seem high. Saturday, noon local with supposedly good propagation, I'm only hearing maybe a half dozen different conversations and many of those only one end.

I've run an antenna analyzer from the connection at the transceiver out and the sweep looks pretty normal.

I'm not sure what to expect from this hybrid rig. Still very new at all this. Thanks for any suggestions.

With an antenna at 20 FT,on 20M, that's about what some neighborhoods in suburban areas can expect. Raising the antenna a lot higher may give you a better S/N ratio. Doing some detective work with a portable radio around the house , unplugging appliances and Entertainment gear like computers, big TVs and TV cable modems and wall warts may help. Running around the neighborhood near power poles may reveal external noise sources. It takes some effort.My noise floor varies from S0 to S7, buzz or crackling noise in rainy or very dry , dusty WX due to bad power line insulators in the area. The -6VDC source is on the FIX CH AVR Unit PC board on the terminal labeled "-6". Look at the PC board's Xray view on page 29 in the TS-520 Service manual. The -6 terminal is clearly shown in the Xray view of the PC board making it very easy for you to find.

If you do not have the operator and service manual for your model of TS-520 (look below the VFO knob and you will see which model you have, there are 3 different 520 models), you should not attempt to service your 520 without them. I have them both on my website for free downloading.

www.w5rkl.com

in the "Manuals and Document" page on the Kenwood Manuals and Documents page. Click on the link and the pdf manual will download to your computer.

Just got a TS-520SE and am going to be running a MFJ G5RV antenna (1.8 - 10 meter) for the moment. I also have a 40M antenna that I am also going to set up and run.
Here are the Q's
The MFJ G5RV feedline terminates in an So239.
1) Should I run a 4:1 or a 1:1 balun? Or make a coax wrapped balun on 4" pvc?
2) Do I need an antenna tuner or Should I run an antenna tuner just for safety? I have a MFJ 949E
3) IF this radio needs care or service who can I get to work on it in Texas? The USA? I have been following the posts of those here working on theirs and I fear should I mess with mine I would kill it. I am not a transceiver repair person. Maybe if I had someone to walk me through it all hands on, MAYBE... I can rebuild engines, wire houses, plumb house, frame houses. I can replace roofs, I can solder and weld run a lathe.... work on the TS 520.. not so much
Thanks

Mike, thanks for your reply.

I found the -6vdc source and the FIX ch board. I am getting -3vdc and on the 9vdc I am getting 3.97vdc and on the 14vdc I am also getting 3.97vdc. I tried adjusting VR1 for the 9vdc and it only changed a few MVs. The only caps I have not changed are C19 and 20. I plan on replacing them next week and the single electrolytic cap on the RF unit. Can't figure out how to get to that one. Q3 and 4 on the AF unit are super super hot.

Thanks
Carlos

You definately need to connect a tuner, the G5RV has medium poor to real bad high SWR on all bands, Balun? if it has one it is at the junction of the balanced line and coax run already. or just connect what ever length of coax needed to reach the shack. .The "special" length of balanced line is supposed to make the SWR lower on 20M if it is the original length G5RV, Some modified versions are longer and not as good on 20M as the original design. Have fun.   My radio is Ham Radio...CW is Real Radio

Bill,

You did not specify the overall length of the G5RV you have.

A tuner is required for maximum efficiency and power transfer to the antenna. I used a 102 foot G5RV using a Drake MN-2000 tuner and worked tons of stations on 40 meters, even DX without any problems.

Why would you think you need a "4:1" balun? The impedance at the base of the 450 ohm feed line with the SO-239 is 50 ohms. You also do not need a 1:1 balun unless you experience RF problems. The G5RV instruction should tell you this. I used an 102 foot G5RV for 5 years and the instructions clearly stated the only time a 1:1 balun is needed is if the operator experienced RF problems in the shack. Other than that you don't need a balun. A length of 50 ohm coax connected between the tuner and the SO-239 at the end of the 450 ohm line is all you need.

Tune the TS-520SE into the MFJ-949E built in dummy load. Once the transmitter is tuned properly, switch to the antenna and adjust ONLY the tuner control. Do NOT touch the TS-520SE PLATE and LOAD controls when adjusting the tuner for lowest SWR.

The TS-520SE has a maximum DC input power (CW mode) of 160 watts resulting in an approximate CW power output of 96 to 100 watts at the rear antenna connector.

I can't tell you who works on Kenwood TS-520SE's in Texas. Maybe other members can tell you who in Texas works on Kenwood hybrids.

If you do not have the operator's manual, I highly recommend you download it on the web and spend time reading it before you attempt to operate your TS-520SE. I have the abbreviated TS-520SE manual on my website but I have the complete TS-520S manual also. You can find them on my website

www.w5rkl.com

by clicking on the Manuals and Documents link at the top of the page.

The only difference between the TS-520S and the TS-520SE is the TS-520SE is designed to operate from 120/240VAC AC power ONLY!!

Carlos,

I don't know why you swapped out "all electrolytic" caps other than you were convinced by someone who said because the caps are old they must be replaced or an ebay seller who's selling KW hybrid capacitor replacement kits. The only time you should replace a capacitor is if a capacitor physically leaks from the pressure relief valve on the positive end of the capacitors or through troubleshooting results that clearly points to the capacitors as the source of a problem. "Shot gun" capacitor replacement as well as resistor replacement is common among new hams today. This method can easily result in creating additional problems the radio did not have such as cracks/breaks in PC board foil runs and wire wrapping problems when removing the boards or pulling plugs off PC boards.

Check the Rectifier Unit's "14" terminal which is the 14VDC supply. That's also the 14VDC source voltage for the FIX CH AVR Unit's "14" terminal voltage. it's possible Q4 on the FIX CH AVR Unit has failed.

I have a high definition schematic with voltages for the TS-520S on my website. The following link will download that file to your computer.

http://w5rkl.com/wp-content/uploads/2014/04/TS-520S_LARGE-Schematic_Hi-Res.pdf

Bill

Take a look at these articles:

http://www.nc4fb.org/wordpress/zs6bkw-multi-band-antenna/

http://www.w0btu.com/g5rv_antenna.html

http://www.reflections.co.nz/wordpress/my-uploads/zs6bkw-antenna-from-the-horses-mouth-by-g0gsf-ex-zs6bkw-sprat-_130-spring-2007.pdf

Many more available with a google search. It is an improved G5RV antenna and needs no tuner on several bands. Might be an easy mod to your G5RV.

Gary

The reason I was asking about the baluns is I do not know the answers. I figure I would get answers from you experts on these Kenwoods. I am learning. I just got my General License this month and am trying to absorb all I can. My G5RV is the 102 foot version. I am hoping to get it about 30 - 35 feet high hung from trees. I wandered by the pawn shop down the road today and bought a really nice Shakespeare reel for 20 bucks, that will couple with a rod and I have the bow out to cast an arrow into the heavens over the trees. The only iffy part is the one tall tree is a hackberry that is slowly dieing, so I figure in a year or two I might errect a mast made from EMT and PVC to string antennas from. I am working on a top T that would be made from nylon rod mated with PVC conduit The hangers would be nylon rods I can turn on the lathe and thread. Just messing with that for the future. As with all new things I want to learn to do it right. I have a huge respect for the equipment (my Dad was a Heathkit builder going back to early 50's as a kid I would help) I know my limits and figure I can get all the help I can use from those who have tons of experience. Thanks.

See Message Number 51624 and many others on same topic over the years.

Funny how same topics keep coming back time and time again. I guess due to the number of new members joining and dont think to search the archives? Admittedly keyword search could be easier to use. Nothing Joe can do about that. Not a criticism just an observation.

You can also search on Jonard and find the tool that works, but I would not waste money on it.

Topic: 52153 Message: 52199

Greetings group,
I watch & read with interest, ALL msgs. This topic, as Terry-k9tw mentioned, as well as many others, have been a topic of discussion before.
To see if your question/problem has been asked and/or answered already, go to the group home page, click on "conversations," in the "fill in the box" just above, enter your search criteria...then click on "search group(s)." You will be rewarded with every "conversation" that has the key word(s) you entered. Go and enter "wire wrap tool" in the above mentioned box..and see how many "conversations" are returned,.....a lot, huh?, going back prior to 2009! The "files" section also has LOTS of good info, compiled by group members and stored here you future reference.
When searching the "conversation" area, be specific. If you enter say "bias problem," you'll get EVERY conversation that mentions "bias problem." That could possible return several hundred or more conversations.
Please do not get me wrong here. This group was started to help fix, maintain, or otherwise keep these fine rigs going another 40-50 years. There are many levels of expertise...but PLEASE, take some time to browse the Home Page. Granted, it's easier to just post a question than to do a bit of research on your own. I will say also, that we ARE here to help with your problem...just help US by dong a bit of "home work" first.
Have I upset anybody..probably...but no matter how you word it, or how hard you try, or how "politically correct" you try and be, ya just can't please everyone.
 73 Joe
WB7UQUGroup co-owner

Mike, thanks for the link.
I do have the correct service manual, hard copy of the S model.
I changed the caps on the advice of multiple long time 30+ year operators in our club. As for me, I am a 10+yr operator.

I have 13.10vdc at the rectifier point, at the Fix board I have 4vdc, same at the AF unit and the Generator board.
I think Q3 on the AF unit is bad, its hot enough that started to melt my aliment tool. I did get a sound at the speaker as I was pushing wires to get to the 14 on the AF unit.

Thanks
Carlos

Carlos,

Q3 on the FIX CH AVR Unit is only under power when the FUNCTION switch is set to "FIX CAL" or "FIX". If the FUNCTION switch is set to "VFO" position then no power will be applied to Q3 and Q3 should be cool. Check to see if the "FIX" LED above the VFO dial is lit, that will indicate the FUNCTION switch is set to FIX CAL or FIX.

Measure the voltage on Q4s collector, it should be approximately +9VDC. The Emitter voltage of Q4 should be +14VDC, same voltage as found on the FIX CH AVR Unit's "14" terminal.

Disregard my comment about Q3 on the FIX CH AVR Unit. I misread your response, I was looking at Q3 on the FIX CH AVR Unit. Sorry about that.

Q3 could be bad but you should check the voltage on Q3 to be sure. Use the high res schematic with RED voltages to compare to your measurements.

52203. Hybrid Net Update (May 31, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-05-31 21:13:37 UTC
From: Mark Gilger
Topic: 52203 Message: 52203

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by me, WB0IQK. There
were 19 stations checking in under fair band conditions.

We had the following number of radios checking in.

8 running TS-520(x)
2 running TS-530(x)
3 running TS-820(x)
3 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running a TS-830S with my L4B amplifier.

The Sunday net was run by me, WB0IQK. There were
13 stations checking in under poor band
conditions. We had the following number of radios checking in.

3 running TS-520(x)
2 running TS-530(x)
2 running TS-820(x)
3 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-900 + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome

as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total = 142, Sunday☐s total = 88
December 2014, Saturday☐s net total = 92, Sunday☐s total = 86
January 2015, Saturday☐s net total = 110, Sunday☐s total = 84
February 2015, Saturday☐s net total = 103, Sunday☐s total = 98
March 2015, Saturday☐s net total =80, Sunday☐s total = 51
April 2015, Saturday☐s net total = 59, Sunday☐s total = 29
May 2015, Saturday☐s net total = 79, Sunday☐s total = 48 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

I get the FIX LED.

On Q4 I get 3.5vdc at both E, this is the same voltage I get at the 14vdc post.
I was doing some voltage test from the 14vdc source.
At the VOX I get 13.05vdc so voltage running to that side is good but at the AF and FIX I get 4vdc.

Point of interest at C22 I get the 13.05vdc this lead to the VOX, at C21 I get 4vdc this lead to the AF and FIX sections.

If the DC voltage at the junction of the filter choke and C22's positive lead is 13.6VDC but falls to 4VDC at the junction of the other filter choke lead and the positive lead of C23 then I suspect you have found the source of your problem. To verify this, disconnect the wire leaving the junction of C23 and the filter choke. Measure the voltage again at the junction of C23 and the filter choke. If it's still 4VDC then more than likely C23 is shorted internally. If this is the case then I recommend you replace both C22 and C23 with 2200ufd "25VDC" axial lead caps. The original caps only had a "10%" safety margin. A 25VDC cap will have a much higher, 60% safety margin.

Hi friends.
The DG-1 digital display my TS820 has said enough !!.
Resoldered while the bridges between the two sides of the PCB X54-1160-00 and everything seemed to work fine, but a few days ago that from time to time, would disappear any digit, others changed to "9", but after a while, was returning to work well, but today he has said enough. The display does not look any digit, everything is dark.
I checked if there is supply voltage of the unit and yes.
That may have happened ?.
Any suggestions are welcome.

Topic: 52207 Message: 52207

This weekend, I went to town on a good cleaning of the chassis, replacement of the bulbs with LED's and general interior cleaning (tubes, fan, dust bunnies, and so on). I noticed that there are two wires on the VFO remote socket that are crispy. They had been very hot at some point. It looks like pins 7-8 or 8-9. I'm going to repair these when I'm finished moving into my new QTH. But it just worries me that there may be an underlying problem.

Rafa,

Be sure to clean both the Molex connectors on the bottom of the DG-1 and the top (leading to the display tube). Clean and burnish the through-pin connectors between the two boards as well. With a dark display tube, you may want to check to see if you have voltage to the unit from BOTH the 14V and the 5V supply.

Dave

52209. Re: TS-520S... 2 fried wires on the Remote VFO socket

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-06-01 22:10:31 UTC
From: w5rkl@...
Topic: 52207 Message: 52209

If you look at the TS-520S schematic's Remote VFO socket you will notice the follow Remote VFO pins::

Pin 1 is the VFO signal, both internal and remote VFO
Pin 2 is coax shield ground for pin 1
Pin 3 is ground
Pin 4 is 12VAC for remote VFO lamps and relay
Pin 5 is remote VFO relay, + on transmit
Pin 6 is Calibrator signal (9VDC)
Pin 7 is No Connection
Pin 8 is Power to internal VFO
Pin 9 is 9VDC power for both internal and remote VFO

If either VFO-520 or VFO-820 are plugged into the 520's remote VFO socket, pin 9's 9VDC is applied to the appropriate VFO based on the position of the Remote VFO's Function switch. When a remote VFO is used, the jumper between pins 8 and 9 on the 520's Remote VFO socket must be removed.

The 520S operator's manual has a listing of what each pin is for. You can follow each pin's wiring. I have a high resolution 520S schematic on my website which will help you.

If you are not using nor have a remote VFO (VFO-520 or VFO-820)(plugged into the 520's Remote VFO socket, a jumper MUST be between pins 8 and 9 for the Internal VFO to work.Not other jumpers are required. If the jumper is not present then the 520 will not work, both transmit AND receive will fail because no power will be provided to the 520's Internal VFO.

k9bqo,
You will have to ascertain what each wire from the mic does first. You will have to find which two wires go to the mic element and which two go to the ptt switch. A wiring diagram is in your 530 Instruction/Operators manual. This appears to have an electret element, so you will need find power for it. There may be a 9v battery, or other power source in the base.

James,

You can use a number of high impedance microphones with your TS-530S. And congratulations on your recent acquisition. D-104s, Shure 444s and others would meet your needs. Or you could source a Kenwood MC-50. It just looks cool. But with other than a MC-50 you will need to pay attention to the internal microphone wiring to establish the correct pin outs. On the Astatic and Shure microphones the connection information is provided on the microphone. The MC-50 is plug and play. With others you may need to play a bit with your DVM to figure it out.

Good luck on your upgrade and success with a microphone. You will enjoy many contacts on your 530S, it’s a great radio.

Regards,
Joe N9JR

Hi James,

The DM502B is a CB style base mic and includes
some kind of amplifier in the base (requires 2 x
1.5V batteries). You can find the specifications and wiring details here.

http://www.copperelectronics.com/discus4/messages/7750/101904.html?1190308141

You might be lucky enough that the PTT lines are
paired with the black wire. I suggest you test
continuity between black and red when you press
the transmit button. I would also check that the
shield is not connected to any of the wires you will use for PTT.

Good luck

Lou

You're right Joe, that microphone uses an Electret microphone element which requires DC power to work. Power for the microphone element appears to come from 2 x 1.5V batteries in the base. The DM502B wiring is difficult to find.

The displays in the TS-820 were notorious for this kind of behavior. When I got mine earlier this year, it was doing something very similar. Ii pulled the boards and desoldered every connection that looked problematic, and also added hole-through connections for the main ground trails. It works fine now. There are some earlier threads on this. Howard K4LXY

Hi friends.
Well, the problem has been solved.
Thanks Dave for his idea. I had proven the existence of voltage in the molex connector on the bottom, and that if he had, but the pin number 5, union of the two PCB, there was no voltage, and helped in a good light and a magnifying glass I have seen that the track was cut, so a small piece of wire, I made a small bridge and I together.
Anecdotally, I want to tell you that after checking everything, I've ridden all over again and I checked, and surprise, NOT WORK. In Spanish, we say, "maldita sea," is happening now. He had forgotten to place the worth of external VFO.
Anyway, that's all.
Thank you very much to all. This is a wonderful group.

Thanks for your reply Mike.

I changed the cap with a 25v, easier than undoing the wires.
I get the same thing, so that rules out the cap.
Will I hurt anything If one board at a time I remove the 14v source and see if the voltage at the cap comes back up to 14, if so I know the problem is with that board. If not I solder back up and go to the next board....and so on.

Below is the wiring for the DM502B

Shield = Mic Ground (There is no bare shield wire)
White = Mic
Red = PTT Transmit
Blue = PTT Receive

I believe the mic wiring for the 530S is as follows:

Pin 1 Microphone
Pin 2 Push To Talk
Pin 3 Chassis Ground
Pin 4 Microphone Ground

Any input as to what goes where?

Thanks, James

The suspected board's wire wrapped wire(s) will have to be soldered back
onto the board's posts, not simply wrapped around the posts!

The reason I said to remove the wire from the junction of the choke and
cap was to be sure the cap was at fault.

I suspect you mean to remove the wire at the AF Unit's "14" terminal
since you appear to indicate that board is at fault. If removing the
wire results in the 14VDC returning then the fault would be on the AF
Unit board, possibly Q4 as you initially thought (very hot Q4).

I think Rafa may have committed a mistake that I have made a few times: turned the radio on without an external VFO connected and no shorting plug in the VFO socket. Result: no display, no receive, no nothing! Once you take care of that, everything lights up again! Congrats, Rafa, and good luck with the rig!

Dave

Topic: 52224 Message: 52237

Martin,

You did not specify which 520 model you have, there are 3 (TS-520, TS-520S, and TS-520SE). Look directly below the VFO knob and you will see the 520 model you have.

You also only stated your 520 has no transmit RF output on 10. You did not state whether receive works or not. You need to be more specific and perform test on receive. Turn the 520's Marker ON and tune the VFO to 25Khz intervals to see if you hear the Marker signal.

Until it is determined the status of receive on each 10 meter band switch positions and whether the correct HET OSC crystals for all 3 10 meter positions are present, I would not go the route of a driver tube at this point. The 3 10 meter HET OSC crystal frequencies are listed in the 520 operator and service manual's RF Unit schematic. You should have the service manual for your model of 520 before you attempt to service your 520.

Band switch position - HET OSC crystal frequency
28 - 36.895Mhz
28.5 - 37.395Mhz
29.1 - 37.995Mhz

Look on the rear pane of your 520 and if your 520 has the "HET, CAR, and VFO" RCA sockets on the rear panel (TS-520S and TS-520SE has these factory sockets on the rear panel), connect a frequency counter to the HET socket and read the HET OSC crystal frequency with the Band switch set to each 10 meter position. If you have the TS-520 (White dial) but the added HET, CAR, and VFO socket adapter is not on the rear panel, connect the frequency counter to TP3 on the RF Unit board and read the HET OSC crystal frequencies for each 10 meter band switch setting. Compare the frequencies to the list shown above or on the RF Unit board schematic.

If you do not have the 520 operator and service manuals for your model of 520, you can download them on my website

www.w5rkl.com

Click on the Manuals and Documents link at the top of the page. When the page comes up scroll down the Kenwood listening and click on the appropriate manual for your model of 520. The manual(s) will download to your computer in pdf format.

A lot of TS-520s have been modified by back room/truck stop CB hackers to allow the 520 to operate on 11 meters. You will need to determine if

this has been done to your 520 and/or if each of the 3 10 meter HET OSC crystals are present and each 10 meter crystal is the correct 10 meter frequency that came from the factory.

I have been playing with a TS 520SE, that had not been used for a long time.

Before posting this I have spent a lot of time lurking in the posts and file sections......

After a slow turn on through the variac, I now have it going, without any explosions.... I did have to do some work to get the audio section going, one of the output transistors was shorted as was the driver transistor.
I did find some alterations on the SG switch, the White /red wire was disconnected and the red wire was on the wrong end with a resistor 33K across the pins 1 and 3 of the switch.

The radio looks nice virtually unmolested but has a problem with the TX on both tune and CW. SSB is fine at about 120 watts. It also sounds very good on air (so I am told).

I have Tested the tubes (Including the driver) in another working radio, not that I expected a problem, it was just to reduce the level of things to be done later.

ALC has good deflection on the meter in SSB so the driver tube seems to be working as it should.

To tune the radio I use a 1KHz tone to the microphone 50% mic gain then tune as normal in SSB mode to achieve about 100 watts RF output.

When switched to CW or tune even with the drive on full I get no RF output, or additional Ip current.

HV on the meter is 950V in tune , and 875 in all other modes. SG voltage is 260V on SSB and 135V on tune.
Bias Ip on meter is 60mA on SSB & CW but zero on Tune.Bias voltage at the tubes is 90V RX and 60V on TX.
Drive control makes no difference to any of these voltages from none to full.

Any ideas where the issue(s) may be ???? Please help !!!!

Thanks 73
Kevin

In a message dated 6/4/2015 8:40:32 A.M. Eastern Daylight Time,
TS-520_820_530_830@yahoogroups.com writes:

Martin,

You did not specify which 520 model you have, there are 3 (TS-520,
TS-520S, and TS-520SE). Look directly below the VFO knob and you will see the 520
model you have.

You also only stated your 520 has no transmit RF output on 10. You did not
state whether receive works or not. You need to be more specific and
perform test on receive. Turn the 520's Marker ON and tune the VFO to 25Khz
intervals to see if you hear the Marker signal.

Until it is determined the status of receive on each 10 meter band switch
positions and whether the correct HET OSC crystals for all 3 10 meter
positions are present, I would not go the route of a driver tube at this point.
The 3 10 meter HET OSC crystal frequencies are listed in the 520 operator
and service manual's RF Unit schematic. You should have the service manual
for your model of 520 before you attempt to service your 520.

Band switch position - HET OSC crystal frequency
28 - 36.895Mhz
28.5 - 37.395Mhz
29.1 - 37.995Mhz

Look on the rear pane of your 520 and if your 520 has the "HET, CAR, and
VFO" RCA sockets on the rear panel (TS-520S and TS-520SE has these factory
sockets on the rear panel), connect a frequency counter to the HET socket
and read the HET OSC crystal frequency with the Band switch set to each 10
meter position. If you have the TS-520 (White dial) but the added HET, CAR,
and VFO socket adapter is not on the rear panel, connect the frequency
counter to TP3 on the RF Unit board and read the HET OSC crystal frequencies for
each 10 meter band switch setting. Compare the frequencies to the list
shown above or on the RF Unit board schematic.

If you do not have the 520 operator and service manuals for your model of
520, you can download them on my website

www.w5rkl.com (http://www.w5rkl.com/)

Click on the Manuals and Documents link at the top of the page. When the page comes up scroll down the Kenwood listening and click on the appropriate manual for your model of 520. The manual(s) will download to your computer in pdf format.

A lot of TS-520s have been modified by back room/truck stop CB hackers to allow the 520 to operate on 11 meters. You will need to determine if this has been done to your 520 and/or if each of the 3 10 meter HET OSC crystals are present and each 10 meter crystal is the correct 10 meter frequency that came from the factory.

Go to the Gen board and measure dc voltage at CV wire wrap post as you vary the CAR Level pot. Should see approx 0 to 9.0vdc. Then repeat measurement at CM wire wrap post and should see approx 0 to 0.6vdc. Repeat at the BM wire wrap post. Need variable dc voltage to forward bias Balanced Modulator diodes.

Topic: 52246 Message: 52246

Dear Group,

I will monitor replies shortly to see if this topic is ok for this group. The group has provided the guidance I needed in the past to restore, including re-capping and replacing the finals cage, a TS-820S.

My Kenwood SM-220 station monitor, something I have grown fond of, has developed a shorted winding in the high-voltage windings. I can see it arc when the lights are down, and can see by the layer it is in that it is indeed in the hv leg.

The transformer parallels the input when wired for 120, and provides the following:

6.3 V @ 0.3A
15 & 15 from a center tapped winding @ 0.12 A
150V @ 0.1 A
500V @ 6 ma

Part number : L01-9126-05

The transformer mounts on a bracket at the rear of the chassis, on a bracket with an angle of about 30 degrees to the back panel.

I think the hv winding has over 3000 turns, and am not excited about the prospect of re-building in that I do not own a winding machine.

Any suggestions are welcome!

Hi Terry,
Just got home and checked the points you mentioned and all apear to be close.0 to 9 V on the CV point but only 0 to 0.5V on the other two(CM & BM). RX state, CW and Tune modes, checked also in TX state and numbers are the same.
One thing I didn't mention was that the sidetone functions as it should. Probably unimportant but mentioned it anyway.

Thanks

Kevin

0.5vdc is fine.

So when you attempt to peak the Drive in Tune or CW mode you are saying you have done that with the CAR Level pot full CW and get no ALC indication and no RF drive indication on the RF relative power meter position or on external wattmeter. Is that correct?

Humor me and measure dc voltage at RL and RLT wire wrap post in Tune and CW when you flip to Send. If you have a means to measure RF voltage (rf probe/vtvm, O-scope) measure the Carrier level at CAR post as well.

Kevin:

The reason I asked you to restate the problem statement is to make sure you have tried loading in CW mode as well as in Tune mode.

Also, I forgot to mention if you dont have a means to measure Carrier Sig RF voltage at the Gen board go to the CAR Unit Board and get on the CWT wire wrap post and measure the dc voltage there in Send.

If CWT missing then will need to pull the RL-1 MH4P Aux Control relay (not the Ant TR relay) and clean the contacts. This relay controls auxiliary functions like metering, rx/tx bias, carrier oscillator etc. It is located under the VOX board and kind of a pain to get out. Sometimes helps to lower the metal plate that the adjustment trim pots are mounted on. That way can get two hands at it. Especially helpful if you want to get the hold down wire bale re-installed on it.

I could not find a source for Q3 and Q4 on the TS-520 AF Unit board. My suggestion is, since you would have had to remove the AF Unit board if you were able to find replacements for Q3 and Q4 anyway, I recommend you write Bob Mansker, KE5FTF (ke5ftf at mail dot com) and see if he can provide you with a good AF Unit replacement board. Make sure you turn your board over and write down ALL the numbers on the foil side along with the "X49-0008-01" board number then give all the numbers, foil side and component side, to Bob so he can make sure he gives you the same version AF Unit board.

Hi Terry,
OK I am humoring you !!

Voltage at RL is 0 RX 14.85 TX in all modes CW Tune & SSB

Voltage at RLT is (-1.87V) RX and 9.03V in TX All modes Tune CW SSB

Voltages checked with both DMM and O-scope

With Rigol Specan CAR shows a signal at 3.4 MHz -11dBm on SSB & CW but no signal on Tune & RX

On TX the signal is 3.4 Mhz -11dBm on USB & LSB, But no signal at all on CW otr TUNE

Tuning setup, Bird 43 watt meter with 100 watt slug , Bird dummy load and 1 KHz tone generator.

To tune the radio I use SSB and a 1KHz tone to the microphone, mic gain set to about 50%, this works well and provides a tuned radio, All these tests and voltages have been done with the radio in tune and with the carrier pot at both minimum and maximum levels.

I get no RF out on the bird meter and no difference in the Ip current or ALC on CW with carrier control set from min to max...

I hope that clarifies the situation....

Thanks
Kevin

Kevin.

Ok you have the DC voltages at RL and RLT that you need.

I didnt see any dc voltage measurement at Carrier Unit board at CWT in Tune and CW mode flipped to Send? Should see close to 9vdc at CWT in Tune/CW modes when flip to Send.

It appears you have no Carrier Signal at the Gen board in Tune/CW modes and I believe I discussed RL-1 Aux Control relay contacts as potential source of problem if no dc voltage at CWT? You can prove this by applying 9vdc transistor battery to CWT in Tune mode.

Also are you certain your measured Carrier level isnt 11dBm and not -11dBm. 11dBm would be approx 800mv. -11dBm is about 60mv and would be way too low for proper mixer action.

Topic: 52265 Message: 52265

I am looking for a TS520S tech special. Serial number not important.

Rig does not have to be in good cosmetic condition or functional, but I prefer that it be all there (no PC boards removed etc). OK if tubes have been pulled.

It will not be repaired. It will serve as a "donor" radio to harvest obsolete parts to keep other owners TS520S radios on the air.

Please contact me off the reflector to discuss.

Thanks
Terry K9TW

From: Kevin Quirke
Topic: 52240 Message: 52266

Hi Terry,
I have given some info that was not quite correct.
Carrier board CWT RX -1.8V TX 9V CW mode (White / red wire)
Carrier board CWT RX 9V TX 9V TUNE mode

Carrier board CWR RX 9V TX (-)1.8V CW (Grey wire)
Carrier board CWR RX 0V TX 0V TUNE

After checking my specan against my sig gen,(removing the attenuation) then rechecking the car RF out I found that it is close to 0dBm.
still about 10dBm less than you said it should be too....

I pulled the covers of a mates 520S and his CAR level is 11dBm

Also all the voltages we have checked on mine are the same as his, except for these two.
His carrier level at 11dBm
CWR is -2.2V in both TX and RX on TUNE

I did have the relay out it all looked brand new so I put it back, in not easy.....If it will help I can swap the relay with the one in the other radio...

Thanks
Regards
Kevin

52268. TS-520 Bandswitch / Osc Board issue

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-06-06 18:13:47 UTC
From: scott@...
Topic: 52268 Message: 52268

I have a TS-520 that works great except when the band switch is set to 28.5. At this setting, I have low receive sensitivity, and only a few watts out on TX. Measuring TP3 on the RF board I measure 12.5 MHz at around 280 mV. However, the crystal oscillator is correct, and the TX and RX frequency is correct. I'm assuming frequency measurement error? When I look at the TX signal on my spec an, the carrier frequency is correct, and the output looks clean.

I'm assuming this is an issue on the osc board. I have pulled it, cleaned it, resoldered connections with no improvement. The radio works great when the band switch is set at 28 or 29.1. Also, I have adjusted the osc coil.

Any suggestions would be appreciated, because I am stumped.

73,
Scott

From: va3vfo@...
Topic: 52270 Message: 52270

Is an defective Power-Switch a common problem on this rig?

I have found high RFI speaker noise (and 20 Over S-9 meter indication) is actually being caused by an intermittent contacts in the rigs power switch! It "sounds" like it is within the switch. I can hear the actual "flash-over" and intermittent "zzz-zz-zzz". I can see/hear it from no other device close to switch area. It does NOT always make the audible noise from with-in the switch- but the RFI can still be present.

Leaving it on for 10 minutes it will self- resolve.
Just though I'd add the "high noise" level symptom to the archive-especially if you can not hear the switch flashing over.

If anyone has a good replacement Switch, please let me know. I will also try Kens.

Just to update: I had to board out for inspection - especially of IC3. Retouched a few solder joints, but had to re-install board before further IC testing etc.. (had to temporarily store rig). After closing it up: gave a try, low an behold display working again. Has continued to work perfectly for a few months now, so maybe it was still a bad joint..will see how long it lasts. Not ruling out an intermittent connection on a plug either.
Not going to "fix it while it works"...:-)

If CW receive is working normally then dont worry about CWR dc voltage in Tune mode. Has nothing to do with TX operation.

If you have normal CW receive it tells you that X1 crystal is good and soldering at its pins is good.

If you have 9vdc at CWT in Tune and CW mode when flipped to Send then you should have approx 11dBm level carrier signal at the OUT wire wrap post on the Carrier Unit board on bottom side of the radio.

Should have close to same level in CW receive mode and in Tune and CW mode when flipped to Send.

Have you measured the Carrier Level at Carrier OUT terminal? Where did you measure to obtain the 0 dBm (224mv) signal level?

Also no reason to pull RL-1 if you have 9vdc at CWT when flipped to send. That tells you that contact RL-1-4 is not the problem. No way to look at any relay externally and say it looks "brand new". Must measure contact resistance. If done with ohm meter should read no more than what you see with meter leads shorted.

Only reason to look at frequency at TP-3 is to ensure someone hasnt CB hacked the radio.

You never adjust Het Osc with a Frequency counter. There are no series or parallel trimmer caps to pull the crystal frequency.

You always adjust Het Osc for rf output level on the slow side of the response curve to ensure reliable start. Should see close to 1.0 rms rf volts at TP-3 on all bands.

Have you performed the Het Osc coil alignment noted in the Service Manual Section 3-13? Exercise caution not to break a core or rip coil former off its mounts. Inspect each core with lite to see if any cores are cracked before you start. If cracked that will have to be addressed before you can adjust. Lots of discussion in the archives regards core recovery methods.

Aye if your amp has soft-key installed you can still use with older radios as well as the new rigs, still hook up the same. Gives you the advantage of plugging straight in with a new rig like the old rigs can.

Hi Terry,
Thanks for your help.
I measured the CAR point on the Generator unit, Where you asked....
I also measured it for you just now at the OUT pin on the Carrier unit, the other end of a short peice of coax connecting the two boards together.
On this 520SE it is about 0dBm, on the working 520S it is about 11dBm.

In the last email I gave some measurements that were different between the good one 520S and the not working one the 520SE
Do these mean anything or am I just going around in ever decreasing circles......

Regards
Kevin

52279. Hybrid Legacy Net Update (June 7, 2015)

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-06-08 00:59:55 UTC
From: Mark Gilger
Topic: 52279 Message: 52279

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net started it's existence on November 1st,
2011. The yearly check-in totals are posted at the bottom of this message.

The Saturday's net was run by me, WB0IQK. There
were 12 stations checking in under fair band conditions.

We had the following number of radios checking in.

3 running TS-520(x)
1 running TS-530(x)
2 running TS-820(x)
2 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins
0 running TS-900

I was running a TS-830S with my L4B amplifier.

The Sunday net was run by me, WB0IQK. There were
12 stations checking in under poor good
conditions, although we did have to relocate up
to 14.318. A station was calling CQ on 316. We
had the following number of radios checking in.

3 running TS-520(x)
3 running TS-530(x)
3 running TS-820(x)
0 running TS-830S
0 running TS-510
0 running TS-511
0 running 599 twins

The rest were running non Kenwood hybrid equipment.

He was running my TS-940 + Drake L4B amplifier.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,

although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, and Jimmy, WB2KNR . I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins
Nov. 2013 - Oct. 2014 Saturdays total 842 check-ins, Sunday total 744 check-ins

November 2014, Saturday☐s net total = 142, Sunday☐s total = 88
December 2014, Saturday☐s net total = 92, Sunday☐s total = 86
January 2015, Saturday☐s net total = 110, Sunday☐s total = 84
February 2015, Saturday☐s net total = 103, Sunday☐s total = 98
March 2015, Saturday☐s net total =80, Sunday☐s total = 51
April 2015, Saturday☐s net total = 59, Sunday☐s total = 29
May 2015, Saturday☐s net total = 79, Sunday☐s total = 48
June 2015, Saturday☐s net total = 12, Sunday☐s total = 12 (Month to date)

I think you are telling me that at the OUT terminal on the CAR Unit that you have approx 0dBm and at the Gen Board CAR terminal you have 0dBm when flip to Send in Tune and CW mode.

If you had 11dBm at OUT on Car Unit board and 0 dBm at CAR terminal on the Gen board I would tell you to gently wiggle and tug on both ends of the short coax as you monitored the levels.

What do you have at OUT and Gen CAR terminal in LSB or USB mode?

What CAR level do you have at the GEN board when you are injecting 1khz into the mic line and getting 100 watts out in SSB mode?

If you have approx 11dBm then you know that the X2 and X3 xtals are good, the Q1 Osc is good, the Q2 Buffer amp is good, and the interconnecting coax cable is good. Then just focus on the CWT X1 xtal and CWT bias (which I think you stated is good at 9vdc in Tune and CW mode).

Sorry got you chasing your tail. Not my intention.

Probably someone better able to help you at this point as I have no more ideas. Also apparently you have another rig for comparisons so that is a great way to troubleshoot.

Topic: 52240 Message: 52281

Hi Terry,
I will try to clarify the situation.

The broken 520SE that will not put out any RF on CW or tune has approximately 0dBm on CAR point on Generator board and the same signal on the OUT point on the Carrier unit. The connection between boards is fine.

The 520SE shows this 0dBm signal on (RX) USB LSB CW but notinng on TUNE.

The 520SE on (TX) also shows 0dBm on USB LSB only, but nothing on CW or TUNE

All above measurements taken from CAR on Generator board.

The working radio the TS520S has 11dBm and signal is there on TX and RX in TUNE CW LSB & USB Modes
This 11dB variation between radios seem to make no difference to the SSB signals recieved or the SSB transmissions.

Regards
Kevin

Greetings all. I have a few very basic questions regarding the heater function on my 530S.

1. Should the heater be turned on only prior to transmitting or turned on when I power the rig up? (I have not been turning it on until seconds before transmitting.)

2. If it should only be turned on prior to transmitting how long should I wait after turning it on to key up? (I have been waiting approximately 30 seconds.)

3. If I intend to attempt more contacts should I leave the heater on? (I have been turning it off after a QSO.)

In my owners manual there is a brief description of the CAL switch function. It states the receive frequency can be calibrated at 25 kHz intervals.

My question is, how exactly is this function performed?

Thanks,

James, KD9BQO

Yes. Turn the heater switch on and keep it on. It would be good to have it on for at least a minute or two -- check the manual. That's what allows your finals to transmit. If you are not planning to transmit for some time e.g. you are monitoring a net and you expect a 30 minute wait you can turn the heaters off. In general I just turn the heaters on when I turn on the rig and leave them on.

I'm sure there's a better technical description but for what it's worth...again, read the manual and do what it says.

James,
If you are asking how to use the "cal" function, read Section 4.6 on Pg 20 of your Instruction Manual. With the "cal" switch on, rotate the main VFO knob...you should hear a tone that will go higher and lower as the knob is rotated.....find where there is no tone(zero beat) and adjust according to Section 4.6 If you have a CW filter...then use the highest reading on the S-meter. Again refer to the manual

Kevin:

I forgot to mention that you can also place your RF voltage measuring instrument on the OUT terminal at the Carrier Unit board and try adjusting T1 for maximum RF voltage out. If the radio is new to you it is possible that someone messed with the slug tuned core on this transformer and set it for the 0 dBm output that you are seeing.

If you dont have the Service Manual for the TS520S suggest you down load it. Step 4 describes this adjustment. Also if you look at the TX Level Diagrams around page 43 you will see that it shows 0.87 rf volts level at the Balanced Modulator. 0.87 volts rms = 870mv = 11.8dBm.

Hi Terry,
I have been looking at both radio's today and I adjusted the T1 transformer on the Carrier unit, the signal at OUT came up to about 6dBm MAXIMUM, and the CW and tune problems were gone.

I also checked T1 on carrier board of the 520s and it was peaked at 11dBm on the out pin.

There is still a 5dBm difference between this radio and the TS-520S that I was using to compare voltages and signals, But as it is working well in all modes I can now put it back together....

Tune now provides about 15 watts and CW about 130 Watts on full drive. This is on 20M where all the tests have been done.

Thanks for your assistance.

Best regards
Kevin

Dont worry about what it produces in Tune mode. Only time worry is when not able to get ALC indication and cant peak Drive in Tune. That is almost always due to failed Screen Grid divider resistors R5/R6 56k ohm on the HV board. These are carbon composition and one typically drifts high or open and need to replace both.

Before buttoning up I would take a look at the dc voltage to the CAR Unit board. Need approx 8.4 vdc at BS terminal. It is derived from 9vdc regulated thru the function switch and series diode.

Have you checked and adjusted 9vdc regulated (VR-1) and 3.3 RF-1 (VR-3) at the AVR board? If not I would do that. 1st step in establishing base line performance.

Have fun.

52291. Tuning a hybrid with the AT-230 attached

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-06-09 10:36:19 UTC
From: Martin Jangowski
Topic: 52291 Message: 52291

Hi folks,

my TS-830 works fine now after adjustment and new tubes. I replaced my "old" 20m dipole with a OCF-4band antenna (workable at 40-20-15-10m). I used the dipole without the matching function of the AT-230. However, the one needs a tuner. This is my workflow:

* tune to the desired frequency
* AT-230 to "DUMMY"
* MODE sw. to "TUNE", METER to "ALC", peak DRIVE
* METER to "IP", dip PLATE
* MODE to "CW N", wiggle LOAD and PLATE until max(power) and <=225mA Ip

So far so good. The problem begins when switching to the antenna. The AT-230 manual says something like "switch FWD-REF sw. to 'REF' and minimize reflected power with R TUNE, X TUNE and the band switch". This works fine, I can usually bring the reflected power down to nearly zero.

BUT (and thats a BIG BUT): When adjusting R TUNE and X TUNE, the Ip-meter at the TS-830s fluctuates wildly (sometimes between 100-300mA) and the FWD power at min(REF) is sometimes between 30-50W... not what was intended.

Could someone explain how to do this correctly? One additional problem is that the antenna is rather narrowbanded and needs adjusting for hi-mid-low at the wider bands (like 15m)...

Tx for the help,

Martin DB2MJ

That applies only to the TS-520/TS-520S and TS-820/TS-820S transceivers
that have the DC to DC converter installed to operate from 13.6VDC.

The TS-520SE does not have a HEATER switch nor does it have a DC power
option. The TS-520SE driver and both final tube filaments are ON as long
as the main power switch is turned ON (assuming the transceiver is
plugged into a live AC wall outlet). Kenwood changed the HEATER switch
in the TS-520SE to a CW WIDE/NAR filter switch.

The TS-530 and TS-830 transceivers operate from 120/240VAC power ONLY,
no DC power option was available.

The "HEATER" switch sole function is to provide 12VAC filament voltage
to the 12BY7 driver and both 6146 final tubes. The 6146 filaments are
wired in "series" requiring 12VAC voltage to light the filaments. This
can easily be seen by viewing the TS-530 service manual schematic.

James,

The 6146 filament warm up period is "60 seconds" (see the RCA 6146B data sheet available on my website for further information).

Leaving the HEATER switch turned ON while operating the TS-530 or any of the other KW hybrids that have the HEATER switch, will NOT have any negative affects to the transceiver.

It sounds like your antenna is so far off that the tuner can't completely tune out some reactance and the radio still is seeing a bad load after you attempt to tune . Maybe you have a too long piece of coax between tuner and radio? try a short as possible jumper between the radio and tuner or just try a different kind of antenna.My radio is Ham Radio...CW is Real Radio

Martin, I have a very similar setup, but I use a G5RV up about 35' rather than an OCF antenna. What I did was take my antenna analyzer and using it. mapped out 3 to 4 frequencies in each band I wanted to operate at, and found the resonant point of each frequency adjusting the X Tune and R tune until I had minimum SWR as read on my MFJ-459B. Let's say I've got my analyzer tuned to the 75M band, 3925.0. I set the band switch on my AT-230 to 3.5, turn on and tune my analyzer to 3925 and adjust the input and output caps on the tuner for minimum SWR. That's the resonant point for that frequency, assuming the analyzer is a 50 ohm point. Now, I write the position of XTUNE and R TUNE on a spreadsheet chart. Now reconnect your radio, set your X TUNE and R TUNE to the reading you took with the analyzer. After you've tuned the radio into the dummy load, switching to Ant 1 or Ant 2, whichever you have your OCF antenna on, should get you very close to perfectly tuned. You may have to tweak a bit but you shouldn't have any wild swings. You're seeing those because you're wildly changing the impedance the radio is seeing, since the radio expects to see a nearly 50 ohm load. I'm sure everyone has their own way of doing it. I've found this way works best for me, and I can do this in just a few seconds since after tuning the radio into the dummy load, then switching should only take a few seconds to tweak for minimum SWR. With my TS-530S, I have no problem getting 100W output at about 210ma plate current with maybe 3W reflected. 73Jeff - W5JGW

Thanks for the input, Jeff. Obviously there is no way around an antenna analyzer, as soon as the antenna is installed where it belongs... at the moment, I'm working with a somewhat temporary installation.

Martin, Thanks for the input, Jeff. Obviously there is no way around an antenna analyzer, as soon as the antenna is installed where it belongs... at the moment, I'm working with a somewhat temporary installation.

My initial installation was temporary as well. I initially had the feedpoint of my G5RV at about 24', and the ends were an inverted V, ending about 3 meters off the ground. I did the same procedure, I just re-ran my scan with the antenna analyzer after getting it more permanently installed. The SWR did change after getting it higher up in the air, but I got perfectly good SWR when it was lower, I just couldn't hear as well!! Good luck! 73Jeff - W5JGW

I got the dipole antenna up now, I have the coax in place. I tuned the radio according to the book The tune up process seems to go according to the book as well. The SWRs seem way out of whack on 20 meter. (only place I have tested so far. I was running that all through a MFJ Deluxe Versa Tuner II. The tuner seems to work ok. I do get some low wattage on forward (around 50 Watts unless I talk really loud) The reflected wattage is in the 20 - 30 watt range depending on how loud I talk that seems to give an SWR of 6.

In desperation I put my watt meter from my 2M rig in the antenna loop and get 0 watt output and 0 swr. Not sure if that is because the watt meter is for 2 meters or not. I am not knowledgeable enuf on the electronics to tear into this thing but can do some snooping. I do not know what is wrong. I would really appreciate any and all help. Thanks in advance. Bill,

Place your wattmeter between your tuner and radio. You can remove the other wattmeter. Dipole antennas typically work well only on the band for which they are cut. If you have multiple elements on the antenna for various bands, that will work, but only for the bands you have element cut for.

You will have to tune up the radio, and then adjust the antenna tuner for maximum forward and the lowest possible reflected power. Retune the radio again for the proper dip and loading. These operations may need to be done several times to get to the optimum settings for the band being used.

It takes a little practice to become familiar with this operation. Radios with vacuum tube finals are a bit more difficult to tune especially when using a tuner. I have a TS-520, and have had to go through this too.

Hope this has been some help to you. Good Luck

Bill,

What is wrong is a "2 meter" watt/SWR meter will NOT work on HF.

Also, when you tuned the 520's transmitter, did you tune the transmitter into a 50 ohm dummy load? If not you need to do that. Once you have the transmitter tuned proper as shown in the 520 operator's manual using a 50 ohm dummy load and you switch to the MFJ-941's FUNCTION switch to the antenna, do NOT touch/adjust the PLATE and LOAD controls while adjusting the tuner for lowest SWR. Adjust ONLY the tuner controls for lowest SWR!!!

The MFJ-941 Versa Tuner does not have an internal 50 ohm dummy load. You can purchase an MFJ 260N 300 watt 50 ohm dry dummy load and connect it to the MFJ-941 rear SO-239 labeled "Dummy load". Always tune your transmitters into a 50 ohm dummy load. A 50 ohm dummy load provides a stable resistive 50 ohms to the transmitter.

Bill,

I forgot to ask. What "dipole" are you using? Is it a G5RV or a simple dipole?.

A simple wire dipole can be made by calculating the approximate length of each side of center using the formula

460 / <freq in Mhz>

A 20 meter dipole's overall length, end to end, will be 33.07 feet (468 / 14.150 = 33.07). Divide that by 2 results in each side of center being 16.5 feet long. This is the "Ball Park" length of the dipole. You must now trim the ends on each side, equal amounts, until the SWR is lowest. I usually reduce the length of each side's end a couple of inches each, wrapping the excess wire along the ends. No, wrapping the excess wire along the ends will NOT have a negative affect to the antenna as some hams seem to think. I have been using this method of build dipole antennas for 48 years and it's worked very well for me with absolutely no negative affect to the antenna's operation. I have built dipoles for 80 thru 10 meters using the same method. Antennas on the lower band, 160 and 80/75 tend to have band width limitations, approximately 25Khz at most before readjustments of the length is required. Higher bands tend to not suffer that limitation that much. I use a dipole for 40 meters, calculated, cut and trimmed for 7.150Mhz, middle of the band, and it has worked well with an SWR of no higher than 1.4:1 over the entire band, without a tuner. I also use a dipole on 10 meter, cut and trimmed using the same method and it has a very low SWR, 1.2:1. I operate AM on 10 between 29Mhz and 29.1Mhz and the SWR is flat over the entire band segment. This also will eliminate the need for a tuner on 20 meters.

Hi Mike,
I just hooked the antennas up to the 2 M SWR/Watt meter in desperation. I have the MFJ 949E. It has the 50 ohm dummy which I tuned the radio to using K4EAA's instruction and the owners manual. I set the 60 ma per the manual then followed it all the way. Then double tracked using K4EAA's instruction.
The speaker works fine I had messed with the AF Gain/RF gain knob. (teach me to not mess with things unless the instructions say to . I went outside to check the antenna connections and am about to pull the G5RV dipole down and make sure I didnt mess it up somehow when I installed it.(can you tell I am facing desperation? What I need to do is take a break go eat some pizza then start fresh later tonight.

Got this today. Expect finals are shot. As follows:

Into a 50 ohm dummy load...

1)click send and check ip idle current at 60
2) switch meter to alc and mode to tun. Peg meter with drive knob
3) switch meter to ip , stay at tun, and dip plate to minimum.
4)switch to cw, meter to rf, at this point adjustment of plate and tune gets no meter reading.

Nothing shows on wattmeter, I tried adjusting the rf volt control and nothing.

Réceiver seems to work fine on all bands.

Any suggestions or should I just buy new finals. Very disappointing as I just got this off ebay from someone who assured me finals were good. He lied.

>> A 20 meter dipole's overall length, end to end, will be 33.07 feet (468 / 14.150 = 33.07). Divide that by 2 results in each side of center being 16.5 feet long. This is the "Ball Park" length of the dipole. You must now trim the ends on each side, equal amounts, until the SWR is lowest. I usually reduce the length of eachÂ side's end a couple of inches each, wrapping the excess wire along the ends. No, wrapping the excess wire along the ends

will NOT have a negative affect to the antenna as some hams seem to think. I have been using this method of build dipole antennas for 48 years and it's worked very well for me with absolutely no negative affect to the antenna's operation. I have built dipoles for 80 thru 10 meters using the same method.Â Antennas on the lower band, 160 and 80/75 tend to have band width limitations, approximately 25Khz at most before readjustments of the length is required. Higher bands tend to not suffer that limitation that much. I use a dipole for 40 meters, calculated, cut and trimmed for 7.150Mhz, middle of the band, and it has worked well with an SWR of no higher than 1.4:1 over the entire band, without a tuner. I also use a dipole on 10 meter, cut and trimmed using the same method and it has a very low SWR, 1.2:1. I operate AM on 10 between 29Mhz and 29.1Mhz and the SWR is flat over the entire band segment. This also will eliminate the need for a tuner on 20 meters.

Hi all!

Could someone please explain why you would even need to use an antenna tuner with a hybrid radio
if the swr is 3.1 or lower?
If you read the manuals, they tell you that the radios can handle it on their own, that's one of the reasons you tune the radio.
Isn't using a tuner, which actually tunes nothing but fakes your radio out so you don't blow the finals, a waste of time especially when the radio has a built in tuner of sorts?

I have been using my hybrids for over four years now without a tuner and have never had an issue, even when I was using non resonating antennas.
I'm currently using OFC antennas that resonate fine anyway and never use a tuner regardless of what radio I'm using...

Hi Terry,
Thanks for your assistance !!

After the adjustments to the voltages on the AVR board the reciever is now much more sensitive and alive (3.3 Volt point was 2.3V), with my 2022 sig gen I set the S Meter to S9 for 50 uV signal, reset the zero point, and it is all working very nicely. ALC on Tune is fine now also.

Signal meter and recieve are now almost identical to the TEST TS520s
50uV (-73dBm) for S9 and 1.12uV (-106 dBm) for S1 And can still hear the signal at 0.1 uV or -127dBm.

Is this about normal ??

Kevin

Subject: Re: [TS-520_820_530_830] Re: TS 520 SE No TX on CW or Tune

Dont worry about what it produces in Tune mode. Only time worry is when not able to get ALC indication and cant peak Drive in Tune. That is almost always due to failed Screen Grid divider resistors R5/R6 56k ohm on the HV board. These are carbon composition and one typically drifts high or open and need to replace both.

Before buttoning up I would take a look at the dc voltage to the CAR Unit board. Need approx 8.4 vdc at BS terminal. It is derived from 9vdc regulated thru the function switch and series diode.

Have you checked and adjusted 9vdc regulated (VR-1) and 3.3 RF-1 (VR-3) at the AVR board? If not I would do that. 1st step in establishing base line performance.

Have fun.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <kevinjquirke@...> wrote :

☐
Hi Terry,
I have been looking at both radio's today and I adjusted the T1 transformer on the Carrier unit, the signal at OUT came up to about 6dBm MAXIMUM, and the CW and tune problems were gone.

I also checked T1 on carrier board of the 520s and it was peaked at 11dBm on the out pin.

There is still a 5dBm difference between this radio and the TS-520S that I was using to compare voltages and signals, But as it is working well in all modes I can now put it back together....

Tune now provides about 15 watts and CW about 130 Watts on full drive. This is on 20M where all the tests have been done.

Thanks for your assistance.

Best regards
Kevin

Kevin:

I forgot to mention that you can also place your RF voltage measuring instrument on the OUT terminal at the Carrier Unit board and try adjusting T1 for maximum RF voltage out. If the radio is new to you it is possible that someone messed with the slug tuned core on this transformer and set it for the 0 dBm output that you are seeing.

If you dont have the Service Manual for the TS520S suggest you down load it. Step 4 describes this adjustment. Also if you look at the TX Level Diagrams around page 43 you will see that it shows 0.87 rf volts level at the Balanced Modulator. 0.87 volts rms = 870mv = 11.8dBm.

Terry K9TW

Kevin:

Can you get on the wiper of trim pot VR-1 at the Balanced Modulator? If not, can you get on either cathode or anodes of diodes D6 and D7 at the emitter of Q2 on the Gen board.

If so measure the Carrier (RF signal level) there in CW mode flipped to Send.

Kevin:

Yes -127dbm is pretty good. Rob Sherwood has receiver testing data on his site and as I recall he shows the noise floor of spec tuned TS520 at -139dbm. So MDS would be approx -136dBm. I never measure any at that level. Probably closer to -130dBm.

Other thing you can measure using a calibrated RF sign gen is AGC threshold. This is point where AGC bus voltage just starts down and S-meter should just start up if caled properly. I find it typically around -115 dBm or approx 0.40uv. Need a very high impedance VTVM (around 100 meg ohm) if going to monitor the AGC bus. Otherwise can just watch the S-meter. Not as precise as watching the bus voltage.

If you search the conversations on MDS, Noise Floor, Receiver Noise Gain should find past post where I describe couple of ways to measure and calculate these parameters. Simple test using VTVM with dB scale connected across your speaker or better a 8 ohm dummy load and one using good RF sig gen with calibrated 1uv output and calculator with Log function.

Only a person who is a glutton for punishment would respond to this one!

I believe that the root of this is deeply ingrained tribal folklore and myth exacerbated by modern radios with solid state finals and SWR fold back circuits that protect the PA transistors which are current devices and cant stand the voltages that higher mismatch presents. No relationship to a KW hybrid and its 6146 tube PA and Pi-network tank.

No 6146 in a KW hybrid was ever "burned up" or hurt by reflected power. About worse that can happen is the Plate Load capacitor can arc over and that takes a very high impedance if not loading in to an open.

If you can load into any antenna using the KW hybrid internal pi-network tank circuit then do so. You wont know if the network can handle the mismatch unless you try it. Of course it has limitations both resistive and reactive. Those will become readily apparent to you.

High Z end fed antennas will present a problem and perhaps very short antennas like an 88 foot 80 meter dipole. The KW pi-network more than likely wont be able to compensate for the reactive component of these antennas.

Biggest problem is the additional db loss in the coax feedline due to high VSWR and not burning up a 6146 tubes. Consult the ARRL handbook to see loss for various types of coax. When someone tells you high SWR will damage your 6146 tubes try to get them to specifically tell you how and why? You will usually hear from heat. Where does this heat come from?

Two ways to damage tubes. High voltage and high current. One is usually acute and the other is more chronic. Almost sure way to damage them is to lose the operating bias and go into thermal runaway. Almost no way to hurt them from elevated SWR. Get them to tell you what is the normal RF voltage across the Tank capacitor and across the Plate Load cap at 1:1 swr and then tell you what it is at 3:1 or 5:1 etc. They wont be able to answer (normal is approx 565 rms across Plate Tune cap and approx 71 rms across the Plate Load cap). Note: Do not attempt to measure the RF voltage across the Tank capacitor unless you have the proper test gear.

I have seen a few arced over KW hybrid Plate Load caps and I suspect the initial arc event was due to dirt/dust bridging or insect nesting across the very close plate spacing and not from an SWR excursion. Once an arc has occurred and metal is pitted and transferred almost impossible to prevent repeat arc at that point. I have loaded personal KW hybrids with nothing on the SO-239 and monitored the RF output voltage across the Plate Load cap and about max I have seen is 300 rms RF volts. Less on the 820 and 830 as they have RF negative feedback circuits. Again dont recommend you make a practice of this.

I know very well intentioned folks who feed resonant dipoles and resonant triband trap beams using todays popular Tee match tuners between their KW hybrid Pi-network and the antennas and if they move 10khz and see that reflected come off Zero they adjust the tuner. If it makes them feel better I say have a ball.

I grew up in the late 50s and 60s and most of us used balanced tuners with homemade open wire feeders for our multiband antennas. With popularity of coax and transmitters with built in pi-networks and resonant antennas those tuners were eventually retired by many folks. Hams have been searching for a efficient, reasonable size,coax fed, multiband antenna that can be fed without external tuner for years. Thus the popularity of antennas like the OCF dipole of today.

Of course there is a bit of nostalgia feeding a 135 foot flat top with ladder line and adjusting the balanced tuner caps and roller inductor on the fly as you move around the bands. A Harvey Wells Band Master Z-Match was to be lusted after! I digress.

I don't usually ask a question like this, but what is a TS-830S worth working and in decent shape? I've never owned a tube Kenwood and have always admired them. I'd like to buy one and I plan to start looking for one
I need some kind of benchmark for their value. What interests me in them is their good looks, quality of construction , used parts availability and the many examples of restoration when needed. I'd like to start with one that works and looks good s I am a real newbie to this transceiver. I've worked on many Drakes but never a Kenwood.. ..
Thanks for your time and input..

You do not know how timely this question and topic are for me. I just am starting out on HF and have a great Kenwood TS 520SE hybrid. The manual states that if antenna match is more than 2:1 SWR, then use a tuner. So I got a tuner, but last night was my first night running rig. The tuner showed SWR of 2:1 or more and I could not tune it down (these number came with me talking - just keying mike got only about 1:1 with only 30 watts output) Anyhow, I learn as you all discuss this.
Right now, I am off to the back yard to rebury the coax to my G5RV antenna (I pulled the 55 feet of coax up when the SWRs were over 6:1 but that is another story)Thanks.

Hi Terry
That was very interesting and I would like you comments on my setup please.
I use a 84ft inverted L antenna with 4 10m copper wires buried at 4in under ground in my very small garden, at the base of the antenna is a SGC smart tuner which has been well learnt. I tune into a dummy load and then switch to the antenna and give a breif blast in tune mode which gives me a good match on all bands though not allways perfect. I do not retune the rig (Ts830s).

Date: 2015-06-10 04:06:44 UTC
From: Paul Silver
Topic: 52317 Message: 52325

Can someone explain to me why one would want 30 odd MHz crystals for a band that reads in the 28 to 29 MHz range… this is a serious question… I don’t understand? Please learn me something new… seriously… I have a Kenwood TS 820S and am seeking crystals for the FIX slots… I want to get some for 40m, 20m and 15m, and was thinking I would get the exact crystals for the frequencies I wanted… if this is wrong headed please explain…

I was about to buy them at a highly recommended place, International Crystal phone 800-725-1426

Have a great day!

Best regards,

Paul Silverzweig

Subject: [TS-520_820_530_830] NEED STOCK 10 meter crystals for TS-820

Imagine my surprise, when a TS-820 that I am refurbishing as a gift for a newly minted Technician class ham turned out to have been HACKED for 11 METER USE! Damn!

SO, I need the 4 10 meter STOCK heterodyne crystals from the PLL Assembly to restore this to STOCK, so he can get on 10m SSB

They are:
X7 - 33.5Mhz P/N L77-0493-05
X8 - 34Mhz P/N L77-0494-05
X9 - 34.5 Mhz P/N L77-0495-05
X10 - 35.0 Mhz P/N L77-0496-05

Any help appreciated!

Thanks and 73

-Kevin K7ZS

I have learned in my studies over the last 3 months... there is no perfect antenna that will cover all bands equally well. The only solution is an antenna for each band mounted (around here 70ft up) So, in my quest to get this Kenwood TS 520SE up and running...I am going to cut an antenna for 20 meter. I have one already for 40 meters. The G5RV is already strung in the trees. I am going to take the top pole off the chain link fence (these are the old heavy gauge poles 22' long) and weld two together, mount a length of l electrical PVC conduit on top with a tree with pulleys and eye bolts and a side length of conduit to run coax in the length of this beast. I shall hang an American flag and antennas from this thing. I shall dig a 2 foot hole, fill with concrete and a length of 2" drill pipe and then mount the mast. Since this is Texas, I figure it will take me about 3 months since I also have to relocate the chain link fence east about 3 inches to be 2 1/2 inches inside the property lines.

Seriously though, since I got to move some dirt now is the time to mount a mast..... with a tree on the top I can run antennas up and down and lay with it all.Bill KG5GYL

Only a person who is a glutton for punishment would respond to this one! I believe that the root of this is deeply ingrained tribal folklore and myth exacerbated by modern radios with solid state finals and SWR fold back circuits that protect the PA transistors which are current devices and cant stand the voltages that higher mismatch presents. No relationship to a KW hybrid and its 6146 tube PA and Pi-network tank.

Hi all!

Could someone please explain why you would even need to use an antenna
tuner with a hybrid radio
if the swr is 3.1 or lower?
If you read the manuals, they tell you that the radios can handle it on
their own, that's one of the reasons you tune the radio.
Isn't using a tuner, which actually tunes nothing but fakes your radio
out so you don't blow the finals, a waste of time especially when the
radio has a built in tuner of sorts?

I have been using my hybrids for over four years now without a tuner and
have never had an issue, even when I was using non resonating antennas.
I'm currently using OFC antennas that resonate fine anyway and never use
a tuner regardless of what radio I'm using...

Lee,
Yes there is: your posts are "moderated." You have been a member since Sept 2015...but as you stated you have not posted before. The reason for moderation is simple, and has been explained aud nauseum. The MORE you participate in group "discussions," etc...the faster you get off moderation...this tests your ability to play and function within the group policy/rules.
Also, stated ad nauseum: The moderator(s) and co-owner(s) do not sit around and wait to either approve, or reject messages from persons who are "moderated." We have lives outside of this group...really we do. I'm sorry that we are not able to meet your demanding needs. Also, every member of this group is appreciated...despite what you think. This group is administered for FREE. I wish I got paid.

So, if you feel that this group and it's administrators, do not meet your needs, you can feel free to "unsubscribe" at any time.
I chose to answer this in the group main area so all can see my answer and since the original msg was posted here too.

What, most hams don’t live on an acre or more? For shame!

OK, ok, I don’t either…heh…I too depend on an OCF wrapped around my good neighbor fence. And I do have to use a coupler on 15..all the other bands are 1.5 or less. (80 up through 6) 15 is 2.5 so I don’t really need to ‘tune it’ but…I do like to see that extra 15% of power out! J Candidly, my 820S could care less!

Mike I cant comment very much about your inverted L. Never ran one, but suspect input impedance would depend somewhat on the ratio of the length of the vertical leg to the horizontal leg and be higher with fewer radials or no counterpoise?

Also depends on if cut for 1/4 wavelength on one band or if using it as a multi-band antenna. My guess is if cut for one band that it could be coax fed and your TS830 Pi network cut match it as impedance would be low.

Just about anytime you are trying to run a single wire antenna on 160 thru 10 meters you will find that your Hybrid Pi-network will encounter problems getting a match and you will need to use a transmatch of some type. An auto tuner at the feed point is a nice way to go, but usually not as practical as the feedpoint configuration that an inverted L presents.

Running resonant antennas on the bands that they were cut for you should be able to load using the Hybrids Pi network most of the time.

The point of my post was that there is "SWR-itus" that sees people using a tuner with resonant antennas to ensure anywhere they operate on the 40 meter band using their 40 meter dipole they believe it is critical to have 1:1 match presented to their Hybrid or risk burning up their final tubes.

Never said you wont need a external transmatch with most multi-band antennas.

Topic: 52317 Message: 52335

Paul,

You will find the answer to your question pertaining to FIX FREQ operation by reading the FIX FREQUENCY OPERATION segment in the TS-820 operator's manual starting on page "21". The following is the formula to calculate the required crystal for a specific operating frequency using the FIX FREQ option:

5.5 + <band switch setting> - <desired operating frequency> = Xtal frequency

An example, you want to operate on 14.313. The math calculations would be as follows:

5.5 + 14 - 14.313 = 5.185Mhz xtal frequency

What do the numbers "5.5" and "14" stand for? First you need to know the FIX FREQ crystals simply "replaced" the VFO in certain FUNCTION switch FIX settings. The VFO operates between 5.5Mhz and 5.0Mhz with 5.5Mhz being the VFO's output at the bottom of ALL bands. The VFO does NOT change frequencies when the band switch changes as some hams have been misled in the past to believe. The "14" is the "band switch" setting on the front panel (20 meters). You can calculate other FIX FREQ crystal frequencies using the same formula just change the band switch setting figure then change the desired operating frequency.

  Hi TerryThat was very interesting and I would like you comments on my setup please.I use a 84ft inverted L antenna with 4 10m copper wires buried at 4in under ground in my very small garden, at the base of the antenna is a SGC smart tuner which has been well learnt. I tune into a dummy load and then switch to the antenna and give a breif blast in tune mode which gives me a good match on all bands though not allways perfect. I do not retune the rig (Ts830s).

  You do not know how timely this question and topic are for me. I just am starting out on HF and have a great Kenwood TS 520SE hybrid. The manual states that if antenna match is more than 2:1 SWR, then use a tuner. So I got a tuner, but last night was my first night running rig. The tuner showed SWR of 2:1 or more and I could not tune it down (these number came with me talking - just keying mike got only about 1:1 with only 30 watts output)
Anyhow, I learn as you all discuss this.
Right now, I am off to the back yard to rebury the coax to my G5RV antenna (I pulled the 55 feet of coax up when the SWRs were over 6:1 but that is another story)Thanks.

Topic: 52303 Message: 52342

Let's look at this:

"I got the dipole antenna up now, I have the coax in place. I tuned the radio according to the book The tune up process seems to go according to the book as well. The SWRs seem way out of whack on 20 meter. (only place I have tested so far. I was running that all through a MFJ Deluxe Versa Tuner II. The tuner seems to work ok. I do get some low wattage on forward (around 50 Watts unless I talk really loud) The reflected wattage is in the 20 - 30 watt range depending on how loud I talk that seems to give an SWR of 6. "

Don't know what kind of dipole. Multiband, single band -- Are you using a single band dipole cut for 80 meters and trying to load it on 20? That might give you wacky SWR.

Unless you have a PEP wattmeter looking at wattage when you talk "loud" won't help. Tune the radio as directed and then adjust for your microphone -- per the instructions. The difference between 50 and 100 watts will hardly be noticable. What you should do carefully check the SWR for the range you plan to operate in -- as long as it's 2 or below you should be fine. No antenna will be resonant over the whole ham band -- so cut it for phone or CW and be done with it.

Your 2 meter wattmater is probably calibrated for VHF not HF so any readings you get from this are useless.

My best advice is find someone locally who has an antenna analyzer (or buy one yourself) and use it to make sure your antenna is properly cut for the frequencies you work. If you don't have one start with your dipole a little long, tune into a dummy load, and start checking your SWR.

And before you do anything - turn off your radio and get the ARRL Antenna Book and read it -- especially the chapters relating to dipoles.

Subject: Re: [TS-520_820_530_830] NEED STOCK 10 meter crystals for TS-820

Paul,

You will find the answer to your question pertaining to FIX FREQ operation by reading the FIX FREQUENCY OPERATION segment in the TS-820 operator's manual starting on page "21". The following is the formula to calculate the required crystal for a specific operating frequency using the FIX FREQ option:

5.5 + <band switch setting> - <desired operating frequency> = Xtal frequency

An example, you want to operate on 14.313. The math calculations would be as follows:

5.5 + 14 - 14.313 = 5.185Mhz xtal frequency

What do the numbers "5.5" and "14" stand for? First you need to know the FIX FREQ crystals simply "replaced" the VFO in certain FUNCTION switch FIX settings. The VFO operates between 5.5Mhz and 5.0Mhz with 5.5Mhz being the VFO's output at the bottom of ALL bands. The VFO does NOT change frequencies when the band switch changes as some hams have been misled in the past to believe. The "14" is the "band switch" setting on the front panel (20 meters). You can calculate other FIX FREQ crystal frequencies using the same formula just change the band switch setting figure then change the desired operating frequency.

A good place for inexperienced hams to start learning about tuners/trans-matches, antennas, feed lines, impedance, capacitive and inductive reactance is by studying the ARRL handbook's Antenna section.

Another source is the ARRL book titled "Understanding Amateur Radio" which can be found on eBay and Amazon.com. I'm sure it can be found in such places as school and public libraries as well as used books stores and hamfests. The book has an entire chapter devoted to antennas, balanced and unbalanced feed lines, impedance, inductive and capacitive reactance and how they affect antenna performance.

One option (rather than an antenna analyzer) is to use an antenna noise bridge as a means of adjusting an "antenna tuner" so that it presents a 50 ohm (or "close to" 50 ohm) impedance to the transceiver. It's even possible to build a noise bridge for this purpose; a 9V battery, a few transistors, a zener diode, a few resistors and capacitors (refer to recent copies of the ARRL handbook). Years ago I built such a unit and incorporated it into a MFJ 941 antenna tuner. I did not include the variable capacitor and potentiometer that are typically incorporated into a noise bridge that can be used to actually measure unknown impedances- instead, I built the noise bridge with the "reference" impedance being just a 50 ohm 1/4 watt resistor. Worked great; allowed me to pre-adjust the 941 without transmitting any signal (other than the wideband "noise" from the zener diode, of course.)

Years ago, Palomar used to sell such a device- I think they called it the "tuner upper" or some such.

52352. Re: [TS-520_820_530_830] NEED STOCK 10 meter crystals for TS-820

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-06-11 12:17:21 UTC
From: Mike W5RKL
Topic: 52317 Message: 52352

Karl,

First, you will need the TS-820 operators manual which can be downloaded from my website

www.w5rkl.com

When the home page comes up click on "Manuals and Documents" link at the top of the page. Once the page comes up, scroll down the "Kenwood Manuals an Documents" listing and click on #15, "TS-820S operators manual" link. The manual will download to your computer in pdf format.

Go to page 21 which is the beginning of the FIX FREQ discussion in the manual.

For example, let's assume you want to operate on 14.300Mhz on 20 meters. You use the formula

5.5 + <band switch setting> - <desired operating frequency> = crystal frequency

to calculate the FIX FREQ crystal frequency.

Using the above formula, you substitute "<band switch setting>" with "14" and "<desired operating frequency>" with "14.300". The formula now looks like this:

5.5 + 14 - 14.300

which results in a crystal frequency of

5.5 + 14 - 14.300 = 5.2Mhz

Once you have calculated the desired FIX crystal frequency, International crystals in Oklahoma City, OK can make you the crystal. You simply tell them the crystal frequency, the crystal holder type which is HC-25/U, and the make and model of the transceiver, Kenwood TS-820 in this case. Once you receive the crystal(s) you ordered simply plug them into one of 4 crystal sockets on the FIX VOX Unit board. The crystal socket closest to the edge of the FIX VOX Unit board is X1 which corresponds to the FIX CH select switch position "1". The next socket is X2 which corresponds to FIX CH select switch "2" next is X3 and finally X4.

The front panel "FIX CH" 4 position selection switch, the outer control on the front panel's LOAD control, selects the desired crystal that is inserted into the crystal sockets on the FIX VOX Unit board stated above. The crystals only work when the FUNCTION switch is set to the desired setting (see the TS-820's operator manual page 12 under the

paragraph titled "FUNCTION SWITCH" for the FIX FREQ switch settings "CAL FIX, VFO R, FIX R, and FIX").

I recommend you spend time studying the TS-820 operator's manual, reading the section on FIX CH operation and the FUNCTION switch FIX settings so you fully understand how it works. The crystals used in the FIX FREQ operation simply replace the internal and/or external VFO and the crystal frequency range is the same as the Internal and external VFOs, 5.5Mhz to 5Mhz.

52353. Offending New People For Asking Dumb Questions

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-06-11 12:22:38 UTC
From: wagstw46@...
Topic: 52353 Message: 52353

Regards my response to Jose when he asked why do KW hybrid owners think they need to use a "Tuner" with their radios when their antenna presents a 3:1 SWR I got some off list emails from some newer folks who felt disrespected for asking "dumb" questions. Never my intention. Building and tuning wire antennas is one of the fun parts of this hobby.

My remarks were not directed to any newly licensed person who more than likely has little or no transmitter loading or antenna construction knowledge or experience. We all were at that point early on. My comments were directed to Jose to answer why anyone would think they need to insert an "antenna matcher" in series with an "antenna matcher". His question is a good one. I stand by what I wrote. My belief is based on getting numerous emails and some telephone calls and from face to face discussions with personal ham friends who could not operate their dipole and beams antennas without their MFJ T-match "tuner". On that we agree to disagree.

It is very common for KW hybrid owners to place a popular C-L-C T-match "tuner" in series with the output of the radios internal C-L-C Pi-Match "tuner" to feed their resonant antenna. Again the primary purpose in their minds being three fold. 1. Get more power out. 2. Protect the 6146 finals from damage from "high" SWR and 3. Be able to operate the CW portion of the band on their dipole that is cut for the SSB portion while being protected from items 1 and 2.

One sharp fellow wrote to say isn't the other reason to do this for harmonic suppression especially 2nd harmonic? A very good observation. Of course the real answer there is employing a Low Pass Filter in the transmitter output. Something that most of us did back in the VHF television days. I dont want to call the harmonic suppression aspect of the Pi-network "accidental" engineering, but this double benefit is limited and antenna dependent.

Yes the C-L-C Pi-network does offer 2nd harmonic suppression, but only reliably when loading in to approx 50 ohm resistive load. If you are adding the C-L-C Tee Match unit in series with your rig and thinking it is giving you additional harmonic suppression that is not correct and frankly I had never had anyone tell me that is one of the reasons they employ the unit. This type of "tuner" config results in a High Pass Filter and offers no 2nd harmonic suppression. If the T-match was configured as a L-C-L then you would have a Low Pass Filter, but I dont know of any manufacturers who make this type of T-match as variable inductors are more expensive than air variable caps.

Back to the Pi-network in your Hybrid. One of the reasons that it may or may not offer sufficient 2nd harmonic suppression is due to what kind of antenna you are using. One of the worse case scenarios (and a very real one) is to load your 80 meter dipole on 160. If you are operating your KW hybrid with its Pi-network driving legal limit Amp with its Pi-network on 1.840 mhz CW mode the poor fellows in SSB QSO on 3.680 mhz will certainly not appreciate you!

So to those new folks who are in fact reading the operating manuals antenna section where it does discuss 2:1 SWR limitation when using coax feedline or other transmission feedline

types that present 15 to 200 ohms impedance I commend you for reading the manual and for asking questions. You are doing the right thing. One fellow wrote to say at the end of his license class they told him the very first accessory he needed to purchase is an "antenna tuner". I think if they had qualified it to say if you want to use a single wire multi-band antenna you most likely will need a "transmatch" then they would have been more correct. As some posted there are other options not requiring a "tuner" such as Windoms, OCFs, Fan Dipoles, Trap Dipoles etc.

So sorry to hurt any new persons feeling who is trying to learn. To those who fervently believe that it is a must to use an "antenna matcher" in series with their built in "antenna matcher" with their resonant antennas no intention to hurt your feelings. However, I stand by my comments and feel that you are misguided (not stupid), but recognize your right to operate in this fashion. Just hate to have you perpetuate the myths with new folks. Of course in the end it is harmless.

Thank you to the chap who asked about 2nd harmonic suppression. A good question.

One fellow said it correctly when he posted that antenna "tuners" aren't going anywhere anytime soon and he is correct for multi-band antennas and I suspect resonant dipoles alike.

Please respond off list so we can move on.

Terry K9TW

Hi TerryThat was very interesting and I would like you comments on my setup please.I use a 84ft inverted L antenna with 4 10m copper wires buried at 4in under ground in my very small garden, at the base of the antenna is a SGC smart tuner which has been well learnt. I tune into a dummy load and then switch to the antenna and give a breif blast in tune mode which gives me a good match on all bands though not allways perfect. I do not retune the rig (Ts830s).

Hi Mike,
 I found used copies of the ARRL antenna book as well as a couple other antenna books they put out, they are on the way.
 I just finished cutting wire for a OCF 20 meter antenna and now just need to find a source for the ferrite balun cores. I downloaded the 4nec2 antenna program a few weeks ago and am still trying to figure that beast out. I think that will take a PHD the way it is going.
 I am following the antenna thread closely. Thanks for all the info and the education.73s to all Bill KG5GYL

Bill,

FYI, I looked hard at 4nec2 and came to the same conclusion for antenna modeling. I tried MMANA-GAL (basic is free) and found it much easier and more intuitive to use for modeling. I'm not an expert with it by any means, but I was able to get results that made sense from it and it has both 2D and 3D representations. I believe the basic underlying program is the same as 4nec2 (the VOA antenna modeling equations/software). You may want to give it a look.

Dave

Topic: 52358 Message: 52358

A few months ago, I bought a well-used--but working--TS-520S from a local ham who was reducing his stock of boat-anchors. I'm a newly-licensed ham with no previous experience with hybrids. I'm still getting things set up, so up until today I've only received. However, I finally completed a 50-ohm 100W dummy load and connected it so that I could practice tuning the transmitter per the instructions in the manual.

It seemed to go well, but then again, I don't have any experience to compare it to. One thing I noticed was that the RF VOLT indication pinned the needle so I adjusted the RF Control pot on the side to 2/3 (as instructed in the manual). I went through the tuning process several times, but the RF VOLT level needed to be reset at least once more. The other thing was that the dip for the plate current was very difficult to find, and when I did find it, it was almost imperceptible.

I tuned the unit for SSB several times, then for CW. Satisfied that it was properly tuned, I was practicing the alphabet at about 10 wpm, starting with "a", but before I reached "z" I noticed that the start of each tone was getting weak and a few seconds later the entire thing shut down. No lights, no fan, no sound. I set the unit to RECEIVE and still nothing. There seemed to be a slight burning smell but I'm not sure if this was due to just dust burning off after sitting idle for three months.

Checked the fuse and it's fine. I took the top and bottom covers off and I noticed that one of the 10 ohm 10W resistors on the Final Unit board is cracked. The other identical resistor looks ok but they look old. The schematic shows these two resistors connected in parallel to the cathodes to ground. I'm not sure if measuring them in the circuit is an accurate indication of their true resistance, but each measures about 5.6 ohms in-circuit. I presume that the cracked resistor my be ok cold but may radically change value when hot.

As I bought this radio for only $100, I don't want to spend herculean effort or geld to fix it; it appears that I can replace both of these resistors fairly easily without having to disassemble everything, but I'm wondering: how would this bring the radio back to life? Seems to me that if the unit isn't getting power at all, the issue should be in the power supply, not on the Finals Board. Is a cracked resistor in the Final Unit just a red herring, masking a more serious problem elsewhere?

By the way, it does look like the finals capacitors were replaced a few years ago, and a number of other "repairs" were performed as well. I think the previous owner (who bought the radio second-hand) was very technically competent and I don't think he was a 'golden screwdriver' type. It could be that this radio's time has come. …Or not?

Michael,

You said the fuse is okay. Did you check the fuse with an ohm meter? A fuse can visually "appear" to be okay but be blown. Always check a fuse using an ohm meter to be sure. The main fuse rating should be 6 amp. The final amplifier cathode resistors have nothing to do with the receive.

Did you check the fuse with an oh meter? A fuse may visually appear okay but in reality it's blown. Replace the fuse with a 6amp 120 volt fuse.

Based on what you said about the final amplifier's cathode resistors, I would change both resistor with new 10 ohm 1 watt Metal Film resistors. Mouser sells them under part number:

594-5073NW10R00J
Price Each is 16 cents

If you want to practice sending CW, you do not have to key the transmitter. Simply set the MODE switch to CW, plug a CW key into the rear panel's CW key socket, leave the SEND switch DOWN (places the transceiver in standby/receive) and turn the VOX front panel switch to OFF. With these setting closing the CW key will produce a tone in the speaker but will NOT key the transmitter. You can practice sending CW till the cows come home without keying the transmitter.

For those with limited space who have a tree in the middle of their yard, why not try an inverted vee. You don't have to be exact on the angle at the top and the ends can be above ground about 8 feet, I've had them as low as 5 feet with no adverse affect on antenna performance. I have a 40 meter inverted vee strung from a pin tree limb about 28 feet high and the ends are about 7 feet above ground. SWR is 1.2:1 at the bottom end of 40 meter CW segment. I work DX both Europe and Far East and 98% of the stations I hear and call I work them with 85 watts. I use the formula

468/<freq Mhz>

to get the "ball park" end to end length. I then trim the ends, folding/wrapping each end's excess wire, same amount on each end of about 2 to 3 inches each time, back onto and along the ends until the SWR is lowest at the center of the band.

Just my 2 cents worth.

While tuning on all bands I get very little dip in IP while varying the plate in Tune or CW.

On 14 mHz I get ~82 Watts out into a dummy load.

What is the normal swing in IP when tuning the plate?

I had a similar problem with my TS-830S, was solved with an complete adjustment and a new set of tubes.

The TS-830S manual states "Dip will be typically only about 5mA" and both of my Kenwood hybrids show just a little dip. If you have a power meter, you can see the plate dip as output peak, typically 5-8W RF in position "TUNE". It depends on the band how sharp the dip is (at least at my TS-830). At 40m, it is fairly wide, at 15m very sharp.

Gary,

Try setting the LOAD control fully CCW before adjusting the PLATE control for a dip. The PLATE control dip in IP current should be more pronounced now.

Yes, I did check the fuse with an ohmmeter, and it was ok. But I just looked again and I see two fuses: a 2A and the 6A. I was looking only at the 2A. The 6A is indeed open.

Thanks for the Mouser part #, and also the tip about practicing CW. I didn't know that, but I do have a CW practice setup. I just enjoyed hearing the crispness of the keying on the Kenwood--until it stopped.

Now that I know that it's the 6A fuse, any ideas what could cause the 6A fuse to go? I'm perfectly willing to admit that this all might be attributable to operator error. I was playing with transmitting CW into a 50 ohm dummy load when the fuse blew. The dummy load is 49.9 ohms, according to the ohmmeter. I could just be inept with tuning up the transmitter… maybe I should ask one of the experienced hams in my club to look over my shoulder while I perform this exercise?

Gary,
Your KW hybrid rig makes an excellent tube tester.The Ip dip should be quick and very sharp, on the other hand, a broad, shallow dip usually indicates failing final amplifier tubes.Falling Ip under key down (in CW) also indicates failing final amplfier tubes.Falling "drive" under key down, usually indicates failing driver.
You DO NOT need "matched pair" finals....waste of $$.Buy from reputable dealer....with a return guaranteeMake sure to properly neutralize the new finals

Yes , the manuals say start the tuning, load and dip, process with the "loading" capacitor in the full CCW position. If you have a very broad shallow dip maybe someone has worked on the shaft or replaceded the knob and has the Max CCW position set for minimum engagement of the capacitor plates instead of the maximum !Remember minimum loading in a PI network is Maximum capacitance, full mesh of the plates !~!!!When I tuned up for a 200 mA dip on my TS520 I could get 100 W out on all bands except for 10M, where I got 60-70W out with new tubes usually. I did not operate SSB so I tuned to get 200 mA reading on CW key down. A lot of advisors here push the 220 mA tune-up but the book also mentions running 200 mA for CW. My radio is Ham Radio...CW is Real Radio

  Gary,

Try setting the LOAD control fully CCW before adjusting the PLATE control for a dip. The PLATE control dip in IP current should be more pronounced now.

Keep in mind that with the TS520 & 820, one Fixed freq Xtal can give you a fixed freq for EACH band, for instance a 3550 Xtal is also 7050 when you switch to 40M and 14050 on 20m ETC..... My radio is Ham Radio...CW is Real Radio

Did you get wattmeter reading while you were dipping the plate current?In CW position you have to close key contacts to get RF out, sometimes the shorting contact in the key jack fails to close if there is no key due to corrosion and neglect. Did you hear the CW side tone in the speaker or phones when switched to transmit ? My radio is Ham Radio...CW is Real Radio

Got this today. Expect finals are shot. As foll4)switch to cw, meter to rf, at this point adjustment of plate and tune gets no meter reading.
Nothing shows on wattmeter, I tried adjusting the rf volt control and nothing.

On Jun 9, 2015, at 3:23 PM, Mike W5RKL w5rkl@... [TS-520_820_530_830] <TS-520_820_530_830@yahoogroups.com> wrote:

Bill,

I forgot to ask. What "dipole" are you using? Is it a G5RV or a simple dipole?.

A simple wire dipole can be made by calculating the approximate length of each side of center using the formula

460 / <freq in Mhz>

A 20 meter dipole's overall length, end to end, will be 33.07 feet (468 / 14.150 = 33.07). Divide that by 2 results in each side of center being 16.5 feet long. This is the "Ball Park" length of the dipole. You must now trim the ends on each side, equal amounts, until the SWR is lowest. I usually reduce the length of eachÂ side's end a couple of inches each, wrapping the excess wire along the ends. No, wrapping the excess wire along the ends will NOT have a negative affect to the antenna as some hams seem to think. I have been using this method of build dipole antennas for 48 years and it's worked very well for me with absolutely no negative affect to the antenna's operation. I have built dipoles for 80 thru 10 meters using the same method.Â Antennas on the lower band, 160 and 80/75 tend to

have band width limitations, approximately 25Khz at most before readjustments of the length is required. Higher bands tend to not suffer that limitation that much. I use a dipole for 40 meters, calculated, cut and trimmed for 7.150Mhz, middle of the band, and it has worked well with an SWR of no higher than 1.4:1 over the entire band, without a tuner. I also use a dipole on 10 meter, cut and trimmed using the same method and it has a very low SWR, 1.2:1. I operate AM on 10 between 29Mhz and 29.1Mhz and the SWR is flat over the entire band segment. This also will eliminate the need for a tuner on 20 meters.

73
Mike W5RKL

On 6/9/2015 4:04 PM, Mike W5RKL w5rkl@... [TS-520_820_530_830] wrote:

Â Bill,

What is wrong is a "2 meter" watt/SWR meter will NOT work on HF.

Also, when you tuned the 520's transmitter, did you tune the transmitter into a 50 ohm dummy load? If not you need to do that. Once you have the transmitter tuned proper as shown in the 520 operator's manual using a 50 ohm dummy load and you switch to the MFJ-941's FUNCTION switch to the antenna, do NOT touch/adjust the PLATE and LOAD controls while adjusting the tuner for lowest SWR. Adjust ONLY the tuner controls for lowest SWR!!!

The MFJ-941 Versa Tuner does not have an internal 50 ohm dummy load. You can purchase an MFJ 260N 300 watt 50 ohm dry dummy load and connect it to the MFJ-941 rear SO-239 labeled "Dummy load". Always tune your transmitters into a 50 ohm dummy load. A 50 ohm dummy load provides a stable resistive 50 ohms to the transmitter.

and the thing to to keep in mind in regards to this...the difference in output between a 2:1 and 1:1 SWR at normal power levels probably isn't noticable in terms of S units. If you have 10 watts of reflected power on 100 watts of output no one will notice -- especially with CW.

In the day people loaded fences, metal drain pipes, etc. and got out. Does this matter? Yes. Should we obsess about it? Probably not. Probably adding 20 feet to your antenna height and paying attention to the radiation patterns will probably give as much benefit as obsessing over having a perfect 1:1 SWR across the entire ham band.

I got this to work with around 100 watts about on 40 meters -- about 800 V
and 220 ma key down -- which seems to be normal?? Never had one of these
before so I'm not sure what "normal" is. It appears to be operating like
the manual says it should.

I suspect that there was a sticking relay or a piece of dirt somewhere.
This radio probably hadn't been used for a while. I haven't yet tried it on
voice.

Since your "dipole" is actually a non-resonant G5RV, it will have some fairly high SWR on all bands. You need to have some RF output to adjust the tuner to lowest SWR. Was your tuner set to the "tuned" side of the switch ? If you can't tune out the SWR you either, have some serious antenna/feedline problems or are not adjusting the tuner correctly. It takes some practice to get tuners set correctly. !YOU CAN'T "TALK" while adjusting tuners or reading power/SWR meters! You have to do this in the CW mode with a steady carrier going out.This is impossible in the SSB mode !Good Luck ! My radio is Ham Radio...CW is Real Radio

Michael,

When the 2 resistors are properly connected to the final amplifier (soldered in place) the total final amplifier cathode resistance is approximately 5 ohms at 2 watts

10 x 10 / 10 + 10 = 5

I have a video on my website where I show on a White board, using ohms law formulas, how to calculate the approximate final amplifier cathode voltage, the current flowing through the IP meter circuit, and the DC voltage that is applied to the meter with 350ma of final amplifier cathode current (IP current displayed on the meter).

http://w5rkl.com/videos/

Click on the Kenwood IP meter Operation listing, #1. The video will give you an understanding of how the IP meter circuit works.

Ummmm Probably not adjusting the tuner correctly. Why can I say this????? Well I talked to the MFJ folks yesterday and it appears you can spin then transmitter and antenna knobs past the marked numbers on the face. I was afraid that there could be damage to the tuner if I went past the "10", there is no stops..... So I was very confused, with a bit of education I now know I can spin those knobs to get good numbers. SO tonight I will be spinning them. I should see much better than the 2:1 I was at. Bill

Subject: [TS-520_820_530_830] New ham with huge problem? TS 520SE

  I got the dipole antenna up now, I have the coax in place. I tuned the radio according to the book The tune up process seems to go according to the book as well. The SWRs seem way out of whack on 20 meter. (only place I have tested so far. I was running that all through a MFJ Deluxe Versa Tuner II. The tuner seems to work ok. I do get some low wattage on forward (around 50 Watts unless I talk really loud) The reflected wattage is in the 20 - 30 watt range depending on how loud I talk that seems to give an SWR of 6.

In desperation . Thanks in advance.

Lost all output on 10 meters. Tried 2 different NOS Driver Tubes. No change. All other frequencies still output 90-100 watts. I'm thinking band switch. What is the best way to get electronics cleaner into the switch. Any other ideas on what else it could be?

I have a TS 820s. Purchased back a few months ago. I know the unit will work but it transmits intermittently, well really very sporadically. and when it stops it does it really well. I truly think there has to be a loose/bad connection as I carried back to the guy I bought it from he was kind enough to work with it for me and it was working. Now the ride back home and it no longer worker. Tried putting CW on all bands and flip send switch with no move on the meter. I have done this several times and still no go. I am really confused and just dieing for the unit to work. We actually found I had wired the mic correctly and it works great. If anyone has any great ideas I sure would appreciate. I really want in the HF world but can't afford newer radios . Plus I ain't gonna lie about it my wife is not real happy with my spending on ham rigs LOL

Thanks
Craig

Craig,
since the rig was "moved," make sure the "SG" switch on the rear is in the ON position, also make sure that the "shorting plug" or suitable replacement, is installed.
Also, I recommend that both relays... the one on the "relay board" and the " transmit/receive" relay, be removed and the contacts cleaned. They look the same...but have different ohmic....(is that a word..hihi) value, and should not be mixed up.

Craig,

Check the rear panel's "SG" Switch. It should be in the "ON" position
for normal operation. The SG switch is located directly below the fan.

Craig,
Congrats on your first contact....a 1 X 1 no less!
You state that the rig now works...this would mean that the "SG" switch is in the correct posit.."ON"... and/or the the VFO shorting plug or suitable replacement is there also.
There are two relays...you have spotted one...the other is on the underside of the rig also...back by the final amplifier tubes...under the silver metal shield. DO NOT GO POKING AROUND HERE while the rig is plugged into the wall.....as there's 800VDC(plus) around these two areas. Unplug, and let rig sit...for about 10 minutes or so..and test to see if there's voltage at the "800" terminal on the rectifier board....ZERO voltage is what you want. If unfamiliar...or unwilling to follow these simple safety directions...can and will make you "SK"...as in dead...have healthly respect for the voltages that are present.
You may have to do a bit of wigglin' after removing the two screws that hold the silver cover on...to get the cover out...so you can get to the relay..it simply pulls out. DO NOT use any abrasive objects on the relay contacts.
And also..what does "I pulled the tuner box out...and....." mean? Also...can you be a bit more descriptive about the ALC being "either to far right or left."?

Joe, The box I am speaking of is the tuner dial box That the main tuning knob connect too. When trying to tune the ALC in CW mode it just goes straight to the right of the meter no adjustment. Sometimes tuning the plate switch it will go totally left 0. I found a relay on the bottom of the rig about 1/3 of the way up from the Final tubes towards the front.

I also still not sure how long it should take the watt meter start moving once I switch to CW and flip the send switch. I can make a small video and post on youtube and explain me better if needed

Thank you again

Craig,
Where are you getting your "tune up" instructions from?? Do you have the proper manual for your rig?
With the rig properly tuned up...and then put in the transmit mode(CW) RF output power should be immediate. How are you measuring your output?
The "tuner box" is called the VFO. The other relay...as I stated prior, is also on the underside of the rig..in the upper left hand corner, under the silver metal shield...by the final amplifier circuit board. This is with the rig bottom up, and the front facing you.
When your "ALC" goes all the way to the right in CW...does turning the "CAR" control more counter-clock-wise...reduce it?
It sounds as you are relatively new to the "having to tune the radio crowd." It takes a bit of skill and PRACTICE! Do not keep the radio in transmit for more that 10 seconds or so with the final tubes out of resonance...real bad for the finals!
Ken Kemski has a good step by step tuning guide at his web site k4eaa"dot"com.
Also, good quality manuals (free) can be had from: n6wk"dot"com and also w5rkl"dot"com
Mike, who is the latter call, is an active member of this group

Joe:

Maybe have him go to You Tube and watch Alan W2AEW video on how to load a TS830. Seeing plus reading might help?

Only issue I have with it is Alan shows keeping the ALC indication within the black printed scale during peaking the Drive control which is meaningless, but if it is better from human factoring perspective to teach that step then so be it.

Otherwise it is probably the best video out there.

Craig,

You asked:

/*"Is it right for when I put swith to cw to tune and then flip the heater button and send buttn that it take 10 to 20 seconds for the meter to start moving?*//*"*/

The answer to your question is no. You do not flip the HEATER switch ON then immediately flip the SEND switch to key the transmitter. If I may asked, where in the TS-820 operator's manual did you read that you should follow that procedure?

You said:

"/*Can't use the ALC for tuning as it is either far left or far right*/."

The reason the ALC meter is pegged fully to the right is more than likely caused by you setting the CAR control too high. Rotate the CAR control CCW so the ALC meter indication drops back to less than 3/4 scale then continue adjusting the DRIVE control for a peak indication.

What transmitter tuning procedures are you using? Do you have and did you read and follow the TS-820 operator's manual transmitter tuning procedures?

Do you have a 50 ohm dummy load with a power rating of at least 300 watts? You should be tuning your transmitter into a 50 ohm dummy load. A good 50 ohm dummy load is the MFJ-260C which has a power rating of 300 watts. The TS-820 has a normal power output of approximately 100 watts. Therefore, the MFJ-260C can withstand 100 watts continuous power for 90 seconds with a 2 to 3 minute cool down period. I have and use an MFJ-260C on my bench and never experience any problems as long as I follow the manufacturer's power level and cool down periods.

I don't understand why you removed the VFO (tuner box as you referred to it)???

Did you ask the seller what he/she did to make the 820 work?

Did you check the SG switch to ensure it's set to ON?

You did not mention the VFO-520 or VFO-820 were connected to the rear remote VFO 9 pin socket. Therefore, did you check to see if the required jumper between pins 8 and 9 on the remote VFO socket is making good contact? This is pointed on in the 820 operator's manual (jumper plug). Without the 9 pin jumper plug, all you need is a wire that connects pins 8 and 9 together. Without the jumper installed or making good contact,

the internal VFO will not have any DC voltage, hence the 820 receive and transmit will fail.

Craig,
Before going any further, If you don't already have one, obtain the Operators/Instruction manual for your rig. Read it, and then read it again with the rig sitting in front of you, so you may identify and locate the controls being talked about. Familiarity with the rig and it's controls, and how to properly operate it...goes a long way in solving/eliminating problems. Take some "dry runs." The whole tune-up procedure should take no more than 30 seconds...most of us can do it in a bit less..but that comes from years of PRACTICE.Read the response from Terry-k9tw regarding a YouTube video. The link to it is in his response. I agree it will help. Mike-w5rkl, also makes some valid points. It is important that any explanation you supply to us is clear.
So, take some time, watch the video, read the manual Take some notes regarding your problem(s) and send them to us...we'll help as much as possible

52392. TS-830 Coma... No display, TX or RX

Yahoo group: TS-520_820_530_830 (2015 — 2016)
Date: 2015-06-13 07:37:57 UTC
From: kevin@...
Topic: 52392 Message: 52392

So tonight I replaced the driver tube and the rig worked fine for a few minutes and then the display went black and the TX/RX functions died.I put the old tube back in but still have the same results. Here's the rundown:

Replaced the tube and powered rig up
Listened on 20 meters and tuned the rig to check and make sure new tube was working
Switched to 40Mtrs, started to tune the rig and within seconds it went deadish...

Meter lights work
Tubes glow when heater is turned on
NO ALC
HV is 900 on the button
Idling current shows 60mA
Condition affects all bands
Only an even white noise comes out of speaker. Turned the dial from stop to stop, same noise all the way through.
SG switch on

What I've done so far to try and fix it:
Loosened/re-tightened the screws holding the PCBs
Wiggled the connectors

Any ideas?

Since you are losing Rx and Tx and display blanked it sounds like you are losing the VCO signal which is supplied from the PLL board to the RF board by a small black coax cable. Also, you could be losing the VFO signal to the PLL board.

With an RF probe and VTVM or an O-scope you can check the VFO and VCO levels quickly to see if you have them or where being lost at. Check for VCO signal level at TP-3 on the RF board. Should be approx 1.0 rms volts.

Absent test gear you can try wiggling the VFO cable/molex connector at the PLL board and wiggle the Black VCO cable at the PLL board and RF boards. There is also a mini-Din switch in the external VFO connector on rear panel that sometimes is dirty and intermittent. I exercise it with a spare DIN plug.

So tonight I replaced the driver tube and the rig worked fine for a few minutes and then the display went black and the TX/RX functions died.I put the old tube back in but still have the same results. Here's the rundown:

Replaced the tube and powered rig up
Listened on 20 meters and tuned the rig to check and make sure new tube was working
Switched to 40Mtrs, started to tune the rig and within seconds it went deadish...

Meter lights work
Tubes glow when heater is turned on
NO ALC
HV is 900 on the button
Idling current shows 60mA
Condition affects all bands
Only an even white noise comes out of speaker. Turned the dial from stop to stop, same noise all the way through.
SG switch on

What I've done so far to try and fix it:
Loosened/re-tightened the screws holding the PCBs
Wiggled the connectors

Any ideas?

My TS-520 IS singing again!!!

I changed Q3 and Q4 on the AF board and that did the trick. Nice clean audio, I am going to let it run on receive only for the rest of the day before try to transmit.

Thanks for your help.

Success! Thanks everyone for your help. I'm not sure what was loose but I re-seated every connection I could and it came back to life. All is good in the shack again... de KD0RUR

52399. TS820S modification CW filter

I added some photos of how to make CW modification to have wide or narrow.

For this I used the DH switch on the front, rewiring it, and changing the IF2 connector has 3 pins on the IF PCB, on the other it has 4 pins. The position of the connector on the IF PCB is A, ie corresponding to the position of having just installed the SSB filter.

In the photos you can see very well as I have done.
Best regards.

I have watched the video several times, I do have the manual and have read thru it or than once. I have used the tune up page that I found here that has all the great color photos of step by step tuning. Sorry if I amto uneducated in radio for the group.

Here is explanation from my friend Perry that I purchased the unit from and has shown me how to tune..

With the radio in the SSB position (Upper or lower) and I key the mic and with the meter switch in the Alc position the meter goes all the way to righ
t and pegs and if I continue to hold the mic or send key pushed then the meter needle slowly falls back to zero...But the radio works great and shows
full output for each band as I checked it with a friends meter..

52401. I'm Confssed!

I just purchased a Kenwood TS-830S. It is being shipped to me right now. I don't have it yet. It has no speaker so I am looking for one. The manual says the speaker for the radio is a SP-230. However looking around I see speakers with marking like SP-820 and SP-830. Why is this when the manual calls out for a SP-230?
